This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world’s books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that’s often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book’s long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ **Make non-commercial use of the files** We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ **Refrain from automated querying** Do not send automated queries of any sort to Google’s system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ **Maintain attribution** The Google “watermark” you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ **Keep it legal** Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can’t offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book’s appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google’s mission is to organize the world’s information and to make it universally accessible and useful. Google Book Search helps readers discover the world’s books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at [http://books.google.com/](http://books.google.com/)

London: Printed by William Clowes and Sons, Stamford Street.
COMPLETION OF THE PENNY CYCLOPÆDIA.

The Committee of the Society for the Diffusion of Useful Knowledge, and the Publishers, on presenting the Final Part to the Subscribers, offer a few words of explanation and announcement.

The limits proposed for this work have been exceeded by about one-fourth. To have materially abridged the productions of more than two hundred contributors, not copying other works of reference, but each presenting complete articles from original sources, would have been unjust to the writers, and unsatisfactory to the readers. The result has been that, without trespassing largely upon the indulgence of the purchasers, a Cyclopaedia has been produced without any important omissions, and differing from other books of the same class in not being hurried to a conclusion by abbreviation of the matter contained under the later letters of the alphabet. The complete book may fairly take rank among works of authority systematically conducted without any improper abridgment of labour or expense; and this, although it is the cheapest original work of the class which any time or any country has produced. That cheapness has been made possible, not by any false economy, not by remodelling old materials, nor by employing inadequate writers, but by the expenditure of no less a sum than forty thousand pounds upon the literature and engravings alone, in the assurance that the excellence of the work would secure a large body of purchasers at a small price, who would eventually remunerate the publishers as certainly as a small body at a large price.

The Committee and the Publishers have to offer their thanks to the numerous body of Contributors by whose exertions they have been enabled to bring the work to a conclusion. They have to offer them especially to the Editor, by whose learning, unwearied diligence, and watchfulness, unity of plan has been maintained during eleven years, error, as far as possible, has been avoided, and regular monthly publication, without a single omission, has been accomplished. It is believed that no similar work has ever been brought to its conclusion with anything like an approximation to the same regularity. A list of the Contributors is subjoined.

In the course of publication care has been taken, in all the great departments, to bring up the information to the most recent period, and also to make the later articles supplementary to, as well as corrective of, the earlier. But omissions, especially of new discoveries, improvements, and recent biographies, cannot have been avoided. These will be supplied by the publication, after a proper lapse of time, which will be at least a year, of a Supplement. A full Index will be published at a future day, which will not only materially increase the value of the Cyclopaedia as a work of reference, but will enable the reader to place the later articles in proper connexion with the earlier, in the point of view just mentioned.

December 20, 1843.
LIST OF CONTRIBUTORS.

Editor—GEORGE LONG, A.M., late Fellow of Trinity College, Cambridge, and Professor of Latin in University College, London.

REV. W. ARTKES. General Literature.

Dr. A. ALLAN (late). Classical Literature.

C. C. ATKINSON, Sec. to Univ. Coll., Lond., University College, London, and University of London.

C. BAKER, Master of the Yorkshire School for the Deaf and Dumb, near Doncaster. Deaf and Dumb, Topography, &c.

W. BALEY, M.D. Medicine.

Dr. BARNS, Carlisle. Cumberland, Dumfriesshire.

Rev. J. BRAND, LL.D., Manchester. Manchester; Salford; Schools, Primary.

Capt. BAXTER, R.N., Hydrographer to the Admiralty. North Sea.

Dr. BEAKES (late), Berlin. Antient Medical Biography.

E. W. BESSON. Countessbrough.

Rev. Dr. BILLINGTON. Biblical Literature.

P. VAN BOREN (late), Professor of Oriental Languages and Literature in the University of Königsberg. Oriental Literature, Manus, Mohammed, &c.

J. BOWMAN. General Literature.

J. BREEZE. Arts and Manufactures.

W. H. BROOK, Crystalography.

G. BRUT, M.D. Medicine.

F. BUKS. Mining.

H. S. CHAPMAN. Exchange.

T. COATES, Sec. of Society for the Diffusion of Useful Knowledge. English Law, Biography, &c.

H. COLE. I. S. Office, Seal.

Edw. COPPER, King’s College. Button, &c.

G. L. CRAIG, A.M. History, Biography, General Literature.

R. CULL. Stammering, Voice, &c.

Professor DAVIES, Woolwich. Compass, &c.

J. F. DAVIES, F.R.S., late his Majesty’s Chief Superintendent in China.

J. P. DAVIES. Fine Arts.

H. DAVISON, A.M., Barrister-at-Law. English Law.

Sir H. DE LA BECHE, F.R.S., For. Sec. G. S. Geology.

G. DENT, English Biography.

S. DEPARTMENT. Spanish and Portuguese Literature, &c.

W. R. DEVEREUX. Topography, Biography, &c.

Hon. Capt. DEVEREUX, R.N. Naval Biography, &c.

J. DAVLIN. Shoemaker.

R. DICKINSON, M.D. Materia Medica.

G. DODD. Arts and Manufactures.

Dr. DOWNS, Trin. Coll., Cambridge. Modern Medical Biography, &c.

C. L. EASTLAKE, R.A. Bassano Rilievo: Bologna, School of.

Sir H. ELLIS, F.R.S., Sec. S.A., Principal Librarian of British Museum. English Antiquities.

T. FALCONER, Barrister-at-Law. Law.

S. FERDINAND, Geography and Topography of Ireland.

J. FIELDING. Aquatinta Engraving.

G. FLETCHER. History of the Drum, Boroughs, &c.

WALES, GEOLOGY OF. Though, since the date (1794) of Mr. Aikin's 'Tour through North Wales,' the geological structure of the principality has been actively and extensively examined by Professor Henslow, Mr. Murchison, Professor Sedgwick, and other eminent persons, there still remain some points unsettled in the general classification of the older Palaeozoic strata. These difficulties are now rapidly disappearing under the continued exertions of Professor Sedgwick, Mr. Sharpe, and the zealous members of the Ordnance Geological Survey of Great Britain, directed by Sir H. T. de la Beche. These researches being still in progress, we must wait until the Ordnance surveyors have executed their important task, and solved the grandest and most inviting problem now offered in British geology, by completing a continuous measured section from the Bristol Channel to the Menai Strait, before the whole of the lower strata of Wales can be satisfactorily viewed in one clear and determinate succession of deposits. Still the knowledge we possess of the tendency of these researches is sufficient for a general outline of the mineral composition and organic remains of the whole Palaeozoic series of Wales; and it appears desirable to present such an outline, because it must be in some material points different from the opinions which may have been adopted since the Silurian researches of Mr. Murchison and the Cambrian researches of Professor Sedgwick were undertaken, though not to such a degree as to cause to these eminent persons any but gratifying sensations at the progress toward completion of their arduous undertaking.

When, in 1831, and many subsequent years, Professor Sedgwick and Mr. Murchison made a friendly partition of labour in Wales, each formed for the country he examined the scheme of classification which seemed most suited to his district. Mr. Murchison, parting from the upper limit of what we have termed the lower Palaeozoic series, and working his way downwards through sandy, calcareous, and argillaceous strata (almost unknown, except to Mr. Lewis of Aymestry, and a few intelligent residents in Shropshire, but uncommonly rich in various and successive groups of organic life), established, on a firm basis, the Silurian System; Professor Sedgwick, parting from the lower limit of the same grand series of strata, and proceeding upwards through many thick slates, and conglomerates, and a few thin limestones, in a general sense poor in traces of organic life, proposed to constitute for these the Cambrian system. These 'systems' have been adopted into all our geological works with more or less of confident reliance on their being really distinct and recognisable groups of strata, not merely parts of one grand and varied series of antecedent deposits. But the conterminous boundary of the groups, the exact line, or even the transition zone between them, was never traced. Mr. Murchison was conducted, by his inquiries downward, into the Cambrian system of Sedgwick, perhaps very deeply into it, but without clearly recognising in the slaty and conglomeratic Cambrians the altered shales and grits of the lower Silurians, and without determining the geographical area of these strata. To determine the geographical extent and geological succession of the Cambrian system was left to Professor Sedgwick, a most arduous and complicated task, the work of many years, and yet unfinished. In this labour he perfectly recognised an important truth, which all subsequent experience confirms, viz. that the remains of organic life in the lowest observed fossiliferous strata of Wales were undistinguishable, except by total number and relative proportion of the several classes of antient life, from the larger series of organic remains in the Silurian strata. That the whole of the lower Palaeozoic strata of Wales form in fact one zoological system, was the opinion of Mr. Murchison, expressed in his great work, and from that time a cloud of doubts has gradually deepened over the correctness of the classification which divided this one series of antient life into two systems of stratified deposits. Through this cloud, the only one left on the whole horizon of English stratification, light is breaking by the efforts already alluded to; and we are glad to take this opportunity, the last which may occur, by noticing some points in the geology of Wales, to bring up the knowledge of this subject to the actual date. A short summary of facts will suffice for this end, especially as Mr. Murchison's last address from the Chair of the Geological Society (February, 1843) has touched the same questions.

If a line of section be chosen from the shores of the Bristol Channel (as, for example, about Cardiff) across the mountains and valleys to the Menai Strait (a line actually chosen and partly executed by the Ordnance Geological Survey), it may be made to pass through nearly all the principal formations of Wales in a direction favourable for showing the manner of their arrangement. The general features of such a section may be as under:

---

No. 1.

CAMBRIAN STRATA.
On the shore of the Bristol Channel lies and new red-sandstone, nearly level, and separated from the coal strata of South Wales. From these, on the north side of the coal-field, rise the old red-sandstone and the Silurian strata, conformable in position to the coal and mountain limestones.

The Silurian strata are in their lower parts often confused and somewhat altered by frequent occurrences of trap rocks, and in some places are made to assume a slaty structure, and this even to lose all distinct stratification. When this happens, the lower limit of the Silurian system appears untraceable; but yet, as a mass, the appearance of these rocks is different from the mixed massive and slaty rocks of the central ranges of Wales, which rise to Plym-lymmon, the Berwyns, and Snowdonia. In all of these strata the layers are not uniformly horizontal, but are often contorted near trap rocks (which are bent with the argillaceous and conglomeratic strata), and generally subject to very prominent slaty cleavage. The least confused part of this labyrinth of rocks is in the Snowdonian ranges, at least this is the part on which Professor Sedgwick's views appear most positive. Here strata rising to a thickness of many thousand feet, including slates, conglomerates, and trap bands, succeed one another with considerable regularity, the lower series being (in Mr. Murchison's view) nearly resting upon chertic and micaeous schists, and meeting unconformable beds of mountain limestone and other newer strata. These beds Professor Sedgwick conceives to be several thousand feet below the limestone of Bala, whose geologic relations have been succinctly discussed. Here limestone appeared to himself and Mr. Murchison to dip (eastward) beneath the rocks of the Berwyn mountains, which consist principally of a mass of clay-slate, in which fossils have not yet been discovered. On this point Mr. Sharpe is silent, and, gives as the result of his recent examination the Bala limestone lying in a trough between the Berwyns and Arran Fowddy, and resting on the clay-slates of the Berwyns. But between Bala and the undoubted Silurian rocks the geographical interval varies. Against the northern parts of the Berwyns the Silurian strata come in contact, but their southern parts are girdled by a broad zone of slates and other rocks, whose age is doubtful; that is to say, it is not yet determined whether they are of the last Silurian age or of some earlier date. This is not yet determined; but there is information gathered by the Ordinance Geological Survey in the country north of the Towy, which goes far to justify a certain positive inference.

This section No. 2 may now be consulted for the general view of the ordinary arrangement of the Silurian strata on the Salopian border of Wales.

Here, beneath the coal, mountain-limestone, and old red-sandstone, appears the Silurian system, in four parts, resting against the slaty (supposed Cambrian) rocks of the Berwyns. The beds marked 1 Llandeilo flags, are sometimes slaty; 2, the Carboniferous limestones contain common coal and generally capped by a certain limestone; 3, the Wenlock formation with characteristic limestones; 4, the Ludlow formation, with equally characteristic limestone and peculiar flaggy shales. If this series of strata has maintained its characters in all other parts of the border of Wales, nothing could be more easy than to determine the exact geographical range of the system. But this is not the fact. This series exists in perfection only in the eastern and southern parts of the Silurian system, in Shropshire, Worcestershire, Woolhope, Malvern, Mayhill, and Usk, and does not exist, with the same parts, in Denbighshire and a great part of South Wales. In the latter district their usual composition may be judged of by section No. 3, where, from beneath the old red-sandstone the first Silurian strata which rise to the north are somewhat doubtfully referred to the Ludlow and Wenlock rocks, but are followed by the determinate Caradoc and Llandovery series. In this series is an antecedent arch of some considerable length, the effect of it being a reversal of dip to the north, so that the Silurian strata appear to descend beneath what have been called Cambrian, and have been left under the colour apparatus of the map below. This is confirmed in Mr. Murchison's supposed map. These so-called Cambrian strata are however, certainly for many miles northward of the Towy, nothing but the Llandeilo shales, less calcareous and less fossiliferous. The seeming great dip to the north, which often occurs in these beds, is sometimes fallacious, and in fact is caused by the cleavage planes, here generally inclined to the northwards at about 70°. The true beds have however been traced by Sir H. de la Beche and the Ordinance surveyors, and they are found to be at first highly, then moderately inclined to the north, afterwards to grow flat, and finally have been proved by Mr. R. to undulate and roll into anticlinals and synclinals such as constitute the region of the interior of Wales. Section No. 4 may be taken to represent this—Comparing No. 4 and No. 5, the difference on the north side of the
farther downward, we arrive at the conclusion that beneath the Bala (Caradoc, Woolhope, Coniston) limestone occurs a vast thickness of beds of general mineral characters resembling the mixed shales (or slates) and conglomerates north of Llandilo, which are not in the lowest part of the Llandilo formation as adopted by Mr. Murchison. We further know that in these Snowdonian rocks occur several remarkable fossils or other series of organic remains than those of the Caradoc and Llandilo rocks (or, in general terms, to the Lower Silurian rocks), and must therefore believe that the Snowdonian series is coeval with that north of the Towy, or that it is an earlier stratum than the latter, unless organic remains of similar groups of organic remains. In either case the progress of classification will require the union into one great group of this whole fossiliferous series. Whether any groups which may occur below (as happens in Cambrian) or above (as in the Silurian) groups to or partiality of the rocks in which they lie in his Silurian system. Much importance was then attached to the mineral constitution of rocks and to the chemical composition of the rocks and strata generally, and to the sequence on the surface of life on the globe that geologists have arrived at a decided preference for general classifications of strata founded on their organic contents. There is danger lest this preference become an unjust partiality. In the classification of the fossils, the system of mechanical, chemical, and vital agencies leave out of view the changes of physical conditions and inorganic agencies which preceded, accompanied, or succeeded the changes of the organic world, it must be very clearly proved that the fossils are always and everywhere determined by the series of organic forms, and that these offer general, consistent, and complete types, and are on account to be exclusively adopted. If geologists should generally concede this, we must inquire whether the whole Silurian-Cambrian system possesses such a character of harmony in the assemblages of organic remains in its different parts as to demand its union in one system, and forbid the separation of it into two systems, such as the Devonian system and that below it, which I sometimes have called Paleozoic rocks? This question has not been thoroughly examined. Mr. Murchison, in his general views of the Silurian series, shows that considerable differences appear between the groups of fossils in the upper and lower Silurian strata, at the same time that there is entire identity in the brachiopods, and corals. In our judgment the amount of these differences is very nearly proportionate to that which obtains between the saurian and oolitic formations.

Whoever decides to keep these together in one (the oolitic or Jurassic) system, may consistently unite, even with our present amount of knowledge, the whole of the ancient fossiliferous rocks of Wales (below the old red-sandstone) into one Silur-Cambrian system, or one system of upper and lower Silurians. With this he may combine the view of a general constancy of animal and plant formations, and present state of geological reasoning, general in its basis, and strictly in harmony with the observed succession of organic life. Such a view would be thus stated:

**Upper Palaeozoic Strata.**

- Upper Ludlow formation. (Silurian.)
- Wenlock formation.

**Middle Palaeozoic Strata.**

- Lower Ludlow formation. (Silurian.)

**Lower Palaeozoic Strata.**

- Llandovery formation. (Silurian.)
- Cambrian formation.

Upon this plan of nomenclature the non-fossiliferous deposits below Caradoc may be called Hypostratic Strata.

The materials for this notice are partly supplied from personal knowledge on many of the points discussed, partly from oral communications from the eminent persons whose opinions are quoted, and from the publications referred to. It is to be regretted that Professor Sedgwick's excellent labours in North Wales are in great measure unknown except by incidental notices and abstracts.

(Sedgwick, in Geological Society's *Proceedings*, 1838 et passim; Sharpe, in the same, 1842, 1843; Murchison, *Silurian System*, 1809; *Address to the Geological Society*, 1844, including information of the progress of the Ordinance Geological Survey.)

**WALES, Prince of,** is the title usually borne by the eldest son or heir apparent of the British King or Queen. Before the reign of Edward I, the eldest son of the king was commonly known as Prince of Wales. Edward, the son of King David, 1277, Lewellyn and David, the last native princes of Wales and united the kingdom of Wales with the crown of England. There is a tradition that Edward, to satisfy the national feelings of the Welsh people, promised to give them a prince without blemish on his birth. Edward, in 1301, did not speak a word of English. In order to fulfill his promises, he had sent the queen, Eleanor, to be confined at Carnarvon Castle, and he invested with the principality her son, Edward of Carnarvon, then an infant, and caused the boy to be crucified, which, it is said, was not at that time the king's eldest son, but on the death of his brother Alphonso he became heir apparent, and from that time the title of Prince of Wales has ever been borne by the eldest son of the King. The title however is not inherited but is conferred by special creation and investiture; and was not always given shortly after the birth of the heir apparent. Edward II did not create his son Prince of Wales till he was ten years old, and Edward the Black Prince was not created until he was just thirteen.

The eldest son of the King is by inheritance Duke of Cornwall. Edward the Black Prince was first created duke of Cornwall on the death of John of Eltham, his uncle, who was the last of Cornwall; and by the grant under which the title was then conferred in the 11th Edward III, the dukedom is inherited by the eldest living son and heir apparent. If the duke succeed to the crown, the duchy vests in his eldest son and heir apparent; if it fails to the son, or to the grandson remains to the king, the heir presumptive being in no case excluded. The Black Prince was also created by his father Earl of Chester and Flint. By the statute 21 Richard II., c. 9, the earldom of Chester was erected into a principality, and the Black Prince was created to it, being only to the king's eldest son. Although that statute, with all the others in that parliament, was repealed by the 1st Henry IV., c. 3, the earldom has ever since been given together with the principality of Wales.

A remarkable instance occurred in the reign of the unfortunate Henry VI, in which all these titles were borne by one, not the eldest son and heir apparent of the king. Richard, Duke of York, claiming the crown, procured a act of parliament declaring that after the king's death he, or his heirs should descend in line of his father, to make this succession the more secure, the act declared his eldest son to be forthwith Prince of Wales, Duke of Cornwall, and Earl of Chester. The antiquity of the title of Prince of Wales is of no regular succession, as it were, a confirmation of the father's present right and of his own nearness in succession to the crown. Thus on the death of Edward the Black Prince, Edward III. immediately made his grandson Prince of Wales. Richard III., having made himself heir to the crown, succeeded to it in his turn, and the title of Prince of Wales, in order to strengthen his usurpation. Henry VII., again, on the death of his son Arthur, created his next son Henry, Henry VIII., having no son, created his daughter Mary, Princess of Wales; and after her illegitimacy, his own daughter, having no issue, his own succession had only been heires presumptive, yet they bore the title, being then next in succession to the crown.

The titles, at length, now borne by the Prince of Wales
are, 'Prince of Wales and Earl of Chester, Duke of Saxony, Duke of Cornwall and Rothesay, Earl of Carrick, Baron of Renfrew, Lord of the Isles, Great Steward of Scotland.'

(Selden's Titles of Honour, part ii., c. 5; Connack's Annals of the Province of Wales, 4th ed., vol. ii., 369.)

Wales, New South, extends over the south-eastern portion of Australia. Its western boundary has been fixed by the grant of the colony of Southern Australia, whose eastern boundary extends from the shores of the Southern Sea along the coast to the latitude of 39° S. lat. This boundary-line of New South Wales has not yet been determined, but as Moreton Bay (27° S. lat.) has been settled, and in the interior the sheep-stations have nearly reached the banks of the river Karuah, we shall consider that New South Wales extends to 36° S. lat. The whole of New South Wales is washed by the Pacific, and on the south by Bass's Strait, which separates it from Tasmania, and by the Southern Sea. Within these boundaries it extends from 36° to 39° S. lat. Wilson's Promontory, which constitutes its most southern point, stretches some miles south of 39° S. lat. New South Wales lies between 141° and 154° E. long., the most eastern point being Cape Byron (near 29° S. lat.). Its length from north to south is about 1600 miles, and its average width about 275 miles. This gives an area of 560,000 square miles, or somewhat more than the extent of Portugal, Spain, France and Italy taken together. About one-tenth of this immense country is within the limit of location; but the cattle-stations have a more or less extensive range of country, and the whole of the plains is occupied by mountain-ranges that distinguish that river in its whole course and all the year round. The drainage of the northern portion runs into the Murrumbidgee, which river in this way is likewise supplied with sufficient water to prevent it from becoming dry during the summer months, as is the case with all the other rivers in the plains of the interior. This river is considered as the most important for cultivation which it apparently contains. Nearly the whole of this country was entirely unknown up to 1836, and it cannot therefore be a matter of surprise that more than one-half of its surface has been surveyed only within the last few years, as for the rest it has never been visited by any European. There are no mountains rising within the range of the cattle-stations which are still unknown.

Surface, Soil, and Climate.—The physical constitution of this country is very peculiar. The interior consists of wide plains, interrupted only by comparatively small ranges of hills. The plains are so extensive that these all unite into one river, the Murray, which discharges within the territories of South Australia. On the east and south the plains are surrounded by higher land, which constitutes the watershed between the rivers joining the Murray and those which run to the sea. This watershed is in general met with at a distance of about 100 miles from the shores, with the exception of three places, at two of which itretes to a distance of 140 miles, whilst at the third it is almost at the shore. It has obtained this denomination on account of the great proportion of land fit for cultivation which it apparently contains. Nearly the whole of this country was entirely unknown up to 1836, and it cannot therefore be a matter of surprise that more than one-half of its surface has been surveyed only within the last few years, as for the rest it has never been visited by any European. There are no mountains rising within the range of the cattle-stations which are still unknown.

I. The Australian Alps.—Wilson's Promontory, the most southern headland of Australia, is formed by a mountain, which is distant from the coast by a distance of 15 degrees. This promontory may be considered as the commencement of the Australian Alps, a range of mountains which, for a distance exceeding 70 miles, runs to the west of south, and farther on, for about 100 miles, to the east of north, until it approaches 35° S. lat. So far this range seems to be composed of a single chain, from which several lateral ridges extend to the south-east and west. Its mean elevation does not appear to exceed 2500 feet, and probably it is less at some places. It has been crossed about 46 miles from its southern extremity by this coast, and at this place their surface is about 200 feet above the sea-level. Its activities both on the east and west are gentle, and are partially overgrown with forests, containing many timber-trees, mostly blue gum and black butt. Near 37° S. lat. there are snows above the snow-line, and this portion of it is called the Ajuk Mountain. It extends from the west to east for about 100 miles, but only the western part of it is always covered with snow; it is however not known to what extent, as these mountains have not yet been explored. Above Lake Corangamite the mountains do not appear to rise much above 4000 feet. From the western portion of this range several offsets branch off towards the south-west, which grow lower as they proceed in that direction, and at a distance of less than 100 miles from the sea they assume a gentle slope. The plains of the Murray River, with ridges of high and low hills, near 36° S. lat. From the eastern extremity of the

Ajuk chain (near 37° S. lat. and 148° E. long.), a range extends to the east of north, which always maintains an elevation of from 4000 to 5000 feet above the sea-level, and near 36°30' S. lat. rises to 6310 feet in Mount Kosciusko. This elevated portion of the Alps chain, which is found in February, by Count Strelski, and it would therefore seem that in Australia the snow-line in 36° S. lat. is found below 6500 feet above the sea-level; whilst in Europe, on the southern declivity of the Alps, in 46° N. lat., it occurs at 8000 feet above the sea-level.
bour is hilly, being traversed by ridges connected with the southern portion of the Australian Alps, but it exhibits a considerable degree of fertility, as is proved by several stations which had contested titles for several years before the settlement of Port Phillip was effected. But only the tract immediately contiguous to the harbour is known; the extensive country skirting the western declivity of the Southern Australian Alps, as far north as the Alkalea Ranges, has not been explored.

Port Phillip, situated at the western entrance of Bass's Strait, is a harbour of great capacity. It measures 40 miles from north to south, and as much from east to west in the widest part. The country which surrounds it is to some extent protected by the swells of the sea against the winds. Against the swell of the sea they are protected by the narrowness and the form of the entrance of the harbour, and the shoals which lie before the entrance. The country surrounding this excellent harbour is in general of superior quality. As far as it has been well examined, or to the distance of from 30 to 40 miles from the northern and western shores of the bay, it contains a large proportion of land fit for agricultural purposes; and, in the remainder, with the exception of a few tracts of granite or sandstone, for the formation of open grassy downs. Though the settlement at this place was founded only in 1837, by Sir Richard Bourke, the influx of emigrants has been so great, that several thousand acres have been enclosed since 1840, and numerous herds of cattle and sheep covered the downs. It was then already proposed to divide it into three counties: the northern district, under the name of Bourke, and the western under that of Grant; but beyond this nothing has been done. The country lying to the north-east of the harbour, towards the Australian Alps, appears to offer less advantages, but as no account has been published of it, it would be premature to decide this point.

The North-east coast of Port Phillip the watershed between the rivers falling into the Southern Sea and the Murray occurs about 45 miles from the northern extremity of the harbour, but farther to the west it is between 80 and 100 miles from the sea-shore. On both sides of the watershed the country is hilly and broken, and between 50° and 60°, it rises into mountains. This hilly tract is in general from 30 to 40 miles across. To the south of it is an extensive plain, which descends gently to the sea-shore. Near the sea it is almost level or slightly undulating; but farther north it is excessively elevated, and between 65° and 70°, it rises to 700 feet above their bases. These single hills are most numerous in the vicinity of the hilly tract along the watershed, and among them is Mount Boninyon, which rises 1750 feet high. These hills are covered to a considerable degree of fertility. The worst portion is that which lies due west of the colony of Port Phillip, and extends from the River Numerwillin, or Lea (144° E. long.), to the River Hopkins (142° 43'). It is about 60 miles long, and from 20 to 30 wide, and very wooded, and the best soil is found at their bases. As however the soil in this plain is not of first-rate quality, it has not yet attracted the attention of settlers.

That portion of it however which lies north-west of the colony of Port Phillip, and is comparatively very hilly, is known to have a very good soil, and is well-timbered; probably it will in a few years prove the best of the several tracts. It is however on this plain that the country of the Grampians, though at some distance from them, a very large swamp, which, with several other swamps surrounding it on all sides, covers many square miles in extent.

The best portion of Australia Felix is that which lies within the hilly tract on both sides of the watershed. It is remarkable that nearly all the ridges by which this tract is overtopped do not run in the direction of the watershed. It crosses it near its highest part. On the eastern side these ridges rises to the elevation of mountains, and has been called the Grampians, which name is appropriate if their elevation only is considered, but the extent cannot be compared with that of the Scottish range of that name. The Grampians of the South extend from south to north about 54 miles, between 37°40' and 36°50' S. lat., and occupy a width of 20 miles. They are supposed to consist of two ranges: that seen from the east is called the Serra, on account of its numerous summits, and nearly in its centre is Mount so-called Grampians, which is 4500 feet above the sea-level. That chain which is seen from the west is called Victoria Range. The eastern chain terminates on the south abruptly with two high summits, Mount Abrupt and Mount Sturgeon, which is 1071 feet, above its base. The Grampians are surrounded with extensive forests of fine tall timber-trees of eucalypti.

The country which is drained by the rivers originating in the southern portion of the northern break of the mountains appears to be the most fertile tract of New South Wales. It is abundantly watered by the Nangaeas, or Glenelg, and its tributaries. The soil is black and rich, several feet deep, and rests on a subsoil of clay. In its natural state it is the appearance of a great park, thickly studded with clumps of casarum and other trees, and, as thick forests are not frequently met with, the ground almost everywhere is covered with excellent herbage. But near the banks of the Nangaeas are low tracts, which are somewhat broken, and where the appearance of a mallows and the surface of the higher portion of this plain is strongly undulating, and on it are found many small sandhills. This fertile country is supposed to extend 50 miles from south to north, and somewhat more from east to west along the whole distance from the sea, some cattle-stations have been established in this country since its discovery in 1836.

The hilly tract of the watershed east of the Grampians has by number of rocks, several round hills of moderate elevation, and many narrow valleys traversed by clear and beautiful streams. In some parts the hills are covered with wood; at other places free from wood, but overgrown with grass to the top. All those which are covered with grass afford excellent pasturage, and it is probable that all these tracts are fit for cultivation, but no part of it has been occupied by settlers, except along the road which leads from Port Phillip to the Murrumbidgee.

Between the mountain region of the Australian Alps on the south-east, the course of the Murrumbidgee and Murray on the north, and the boundary-line of South Australia on the west, lie the plains of the Murray River. These plains extend from the sea to a distance of 600 miles from east to west, but our knowledge of this country is very imperfect. We only know that it is very well
W A L

watered, all the rivers which drain it rising in the moun-
tain-region of the Australian Alps, the hilly region of the
watershed, or the Grampians, and that the larger of these
rivers, as the Milawa and its tributary the Bayungs, flow in
wide bottoms, sometimes eight or ten miles across,
which bottoms are overgrown by high trees, partly swampy
or covered with lakes and ponds, but exhibiting an extra-
nodary degree of fertility in the vigour of their vegeta-
tion. In general the water levels are low, or very level or
slightly undulating, and only hilly where they
approach the more mountainous tracts on the south
and south-east. In some places are found salt lakes in con-
siderable numbers, but in general these plains are open,
grounds covered with grassy or low clumps of
wood. Even at a considerable distance from the
hanks of the rivers water is not scarce, as there are nu-
erous hollows in the plains, which generally contain
water; some parts so much so that their waters are con-
sidered valuable for clients after heavy rains. As far as
the plains of the Murray River have been visited by travellers, they are cer-
tainly fit both for cultivation and rearing of cattle. No
settlements have been made in the plains, except along
the Murray for the past two years. There is an area which
they have extended to the west of 147° E. long.; but the
difficulty and expense of bringing the wool and the produce
of the dairies from this distance to Sidney are such, that
of late years the advance of the cattle-stations along the
Murray has not been very rapid. But it is hoped that the plains of the Murray River will be
settled by emigrants advancing from the southward
through the fine country watered by the Nangeela; and to
favour the settlement of this immense tract by a more
extensive and permanent system of settlement, the govern-
ment of New South Wales has lately been established a
settlement at Twofold Bay. This bay extends twenty-six miles from east to
west, and ten from north to south, and has good anchor-
geage on its western shores, in four, five, or six fathoms, it
is open to the south-east winds, and during the south-
western gales gets into the anchorage, causing a
heavy surf on the beach.

As no part of Australia Felix had been settled before 1837, the accounts respecting its climate which we possess are
very few and scattered. From the observations of hasty travellers who have visited it, we learn that
rains are by no means so scarce as in the great plains of the interior or in the countries along the eastern
coast; and as the winds to which this country is most ex-
posable, from March to August, are usually attended with heavy rains, it is supposed that
this country will be less subject to such frequent and
long droughts as the old colony. In winter, frost occurs along the
watershed, and hoar-frost is experienced even on the
lowlands.

III. Gippsland is the name which has lately been applied to
that portion of New South Wales which from the eastern declivity of the southern portion of the Australian Alps and the Ajuk Range descends to the Pacific. The
seven and the sea a ridge of moderately high hills
bears the name of the Long Beach, as in its whole extent, for
200 miles, it extends in a continuous line without any
indentation, curving however a little in the middle. The
shores are low and sandy, but at the back of them the coun-
teries rise into hills. Gippsland extends along this shore from
the Southern Australian Alps to 148° E. long. It consists of an inclined plain, which however near the mountains appears to descend with great rapidity, as in the
mills from which it is raised; but the plain is not above sea-level. The northern portion of this country is traversed by
several ranges of hills, which detach themselves from
the Ajuk Range and run south by east. They are of con-
siderable elevation near the principal range, but grow lower as
they proceed southward, until they cease at a distance of
several miles from the shore. The valleys are of moderate
width, but grow wider towards the termination of the ridges.
The hills are rather steep, but in general well
wooded. The valleys exhibit a considerable degree of
fertility, and some cattle-stations have been established in
them. In the centre of Gippsland are plains of consider-
able extent, which are covered with open forests, and
readily to receive and maintain numerous herds of cattle.
These plains however do not extend to the shore, for be-
tween them and the sea a ridge of moderately high hills
stretches parallel to the sea between the mouths of the
rivers Barney and La Trobe. These hills are thickly
wooded. The southern portion of Gippsland is traversed by several offsets of the Southern Australian Alps,
which are covered with forests of blue, green, and black
bark, in which numerous timber-trees are found. The
whole of Gippsland is abundantly watered by several
streams, running from sixty to seventy miles, but it is not
known if their mouths are deep enough to receive small
vessels. At the southern extremity and on the eastern
ingerie, and on the north-western, are encouraged by
the constant occurrence of small vessels, and full of shools.
It is stated that in the summer months the thermometer at nine o'clock in the morning generally rises to
86°.

The country extending north-east of Gippsland to the river Murray, lies enclosed by the southern boundary of the
settled part of the colony, has not yet been explored in the
interior. At Cape Howe the coast begins to trend due north, and changes its character, being in general rocky
and high, and the plains, which are well watered, are
not so fertile, but which the most important is that of Twofold Bay, a tolerably
good harbour even for large vessels, in which a settlement
has lately been made, from which the adjacent country in a
short time will probably be explored. Not far south of
extension, Mount Dromedary, and rises to 3000
feet above the sea-level.

IV. The Connecting Table-lands. -The most northern
range of the Australian Alps, called the Warragong Chain,
was reached by a party of officials in December 1835,
circling the extremity of this range, changes its northern
course into a western. The Warragong Range extends
nearly south and north, and along its eastern base lie
extensive plains. The most southern of these plains, as
those of Gippsland, are known in the British Colonies by
name of Monero or Monaro Plains, and are famous in the colony
for the large herds of cattle and numerous flocks of sheep
which find there abundant pasture. These plains extend
a considerable distance south of 36° S. lat. Less extensive,
connect to one another and farther north the
eastern portion of the Warragong Range are Yass Plains
and the hilly tract enclosing Lake George. The
extended plains however do not terminate with the range of
the mountains, for there extend the Bredalbane Plains, about forty miles farther north to the
southern extremity of Crowbook Range, which con-
stitutes the southern part of the Blue Mountains. The
last-mentioned plains occupy a width of about fifty
miles, and extend from the southern coast until the
Shoalhaven River runs. Along these plains lies the
watershed between the rivers running east and west, as
some of the sources of the Lachlan and Murrumbidgee,
which run to the west, and those of the Shoalhaven and
Murray, which are found in the southern and eastern part of
gassy land, or of open undulating downs enclosed by
eminences of little height, which separate the plains from
one another: they all afford excellent pasture for sheep,
and cultivation also in many parts carried on with suc-
taneous success. It is remarkable of them is Lake George, a sheet of water
seventeen miles in length and seven in breadth. There is no
outlet for the lake, though it receives no less than four
mountain-streams from the eominences north of it. The
water is slightly brackish, but quite fit for use. In long
droughts it dries up, and then resembles a grassy
meadow, not unlike the plains of Bredalbane. There are several
other lakes to the east and west of Lake George; they are
substantial and the longest of them is 20 miles above
feet above sea-level. These lakes occur at more than 2000 feet above the sea-level, and in winter a considerable degree of cold is experienced on them. Frost occurs for several weeks nearly every
night. As in these parts no mountain-chain separates the
countries lying together, the winters are of
sufficiently good in these parts to grow in them potatoes and gooseberries, for both of which the
climates of Sydney is too hot, grow luxuriantly. The upper
W A L

valley of the Shoalhaven River contains a considerable portion of good land. In proceeding westward the river sinks deeper and deeper under the adjacent plains, and where it approaches its north-eastern great bend it flows in a ravine about 1500 feet below their common level. The precipices of this ravine, consisting at one part of great rocks, and at another of limestone hills, give a peculiar grandeur to the scenery of this part of the Shoalhaven River.

The country to the eastward of Shoalhaven River, that is to say, between it and the sea-coast, is very wild and mountainous. It is full of high hills and short ridges, the summits of which generally rise to a level, which, in places, where the plains west of the river; their tops present sometimes tittle plains, but as the hills are composed of sandstone destitute of a layer of soil, they have as little vegetation on them as the steep declivities of their sides. Near the coast, where these summits are lower, the sandstone is covered by a layer of soil, but with the exception of a few tracts of moderate extent, the soil is poor; it is somewhat better towards the south, but even there of indifferent quality.

The coast is everywhere high, and en er on the coast places where inlets occur, which terminate with low and thinly swampy grounds. Indentations are rather numerous, but none of them can be called a harbour, except Jervis Bay, which is about eight miles long from south to north and three miles wide at any part. Its eastern slope is a great sandstone cliff, and in that part of the coast, from Port Jackson, it still affords good shelter and safe anchorage, being divided from the sea by high rocky masses, and in general it is from 9 to 12 fathoms deep. It is intended to found here a town, and to make a road through the land, for a short, but the country, the increasing settlements on the Murrumbidgee and in Australia Felix may be enabled to produce the their industry with less expense to a place where it can be shipped.

V. The Blue Mountains begin on the south with Cockbundoon Range, near 34° 30' S. lat., and extend northward to the Monundilla Range, which runs from east to west near 32° 40' S. lat. Their length therefore does not exceed 130 miles. Towards the southern extremity of the range its southern slope is the most magnetic. The railway leading from Sydney to the interior, is about 60 miles across; and at its termination in the Monundilla Range, probably more than 70 miles. Its eastern edge runs along the ridge which encloses the Liverpool River, the last of the set, crosses the Warramunga, and extends along the western bank of the Nepean, Hawkesbury, and Macdonald Rivers, terminating at the source of the last-mentioned river in the Monundilla Range. The western edge of this mountain-system has been discovered in 1831. It begins from the sources of the Wollondilly River (149° 30' E. long. and 34° 30' S. lat.) nearly due north, traversing Fish River some miles above Bathurst, at the place where it joins Campbell River, and from this point to run to the east on the high Tablelands of the Blue Mountains Range (150° E. long. and 32° 30' S. lat.). The southern portion of the range, or that contiguous to the Nattai River, does not seem to rise to a great elevation above the general level of the country (2000 feet), but it consists of sandstone, probably destitute of vegetation, and is consequently uninhabitable. Seen from a higher elevation it presents the appearance of a flat country whose surface is hollowed and cracked out into the wildest ravines, deep and inaccessible. No road traverses this part of the range. The only road runs along the ridge which descends from Sydney to Bathurst. It runs along the line of high land which separates the ravines of the valley of the river Cox on one side, from those which belong to the valley of the Grosse on the other. The mountains, it appears, were subjected to an exceedingly steep activity to an elevation of about 1000 feet above the flat country on the banks of the Nepean River.

Farther on, the rise is more gradual, till the highest part of the road, near King's Tablelands, which are the base of the Monundilla Range, is obtained. The face of the mass of sandstone over which the road runs is intersected by ravines, very steep in proportion to their height: near the highest part of the road, the profound depth of the ravines, enclosed by rocky precipices, imparts a wild grandeur to the scenery, hardly to be conceived. The rocks are in most parts overgrown with stunted trees. There is scarcely a patch of land along this part of the road fit for cultivation, except near an inn, which is 2800 feet above the sea, and where gooseberries and potatoes of excellent quality grow. Only two summits, Mount Hunter and Mount Twynam, rising about 12 miles north of the road, rise considerably above the level. The descent from the more elevated part of the mountains at Mount York is not less precipitous than the ascent from the east. West of Mount York the road passes through some deep valleys, which have a peculiar granite, and their surface is thinly wooded and grassy. On Stony Range, the western ridge of the Blue Mountains, the soil is of red colour, rather rich, and bears trees of uncommon magnitude.

The Liverpool Range and the Connecting Ridge.—At the distance of from 60 to 70 miles north of the Monundilla Range is the Liverpool Range, running east and west. This range is of great extent, as the lofty mountains which enclose on both sides the river-basin of the Manunilda, which form the Monundilla Range of the settled part of the country (32° S. lat.), are to be considered as its eastern prolongation. On the west it appears to be connected with the Warrambungle or Arbuthnot Range, which is the exception, rather 1500 or 2000 feet above the base. It appears like a large wall with numerous notches in it, formed of the Monundilla Range, which is a range of hills, from which numerous torrents descend, which feed several perpetual streams. Where the slope is not too rapid, it is thinly wooded. On account of the steepness of the ascent only two places have been found at which it can be traversed with ease. The western, known by the name of Par- dora Pass, is near 150° E. long.; and the eastern, called by the natives Heckmadiey, occurs west of 151° E. long. When the summit of the pass is attained, a short descent brings the traveller to the Liverpool Plains. This evidently an exception, as there is no sign of any inhabited European settlement, and from which numerous torrents descend, which feed several perpetual streams. The Liverpool Range is connected with the Monundilla Mountains by what may be called the Connecting Ridge. This ridge lies between 33°10' and 34° 20' S. lat. It begins on the Monundilla Chain, near 150° 20' E. long., and runs due west for about 140° 30' E. lat. It crosses the New South Wales coast near 30° north-east, and in that direction meets the Liverpool Range some miles east of Pandora Pass. It divides the affluents of Goulburn River, a tributary of Hunter River, which falls into the Pacific, from those of the Cudgegong and Welling River, a tributary of the Charles River. As for the last-mentioned tracts the surface is so level, that the watershed is covered with extensive swamps. A considerable portion of this ridge is without trees, overgrown with bushes and grass; but elsewhere the country is covered with woods of tall trees, iron-bark, stringy-bark, and box. There are some tracts where water is scarce, but in general this ridge is sufficiently watered, and settlements have of late years been made in these tracts (May 1836), and it is probable that the commercial capital of this part of the colony will be transplantated to the mouth of the Hunter River, though the harbour of Newcastle cannot be compared to that of Sydney.

VII. The country between the Blue Mountains and the Pacific.—The line of coast between the mouths of Shoalhaven River (north of 33° S. lat.) and Hunter River (north of 35°) presents a range of bold perpendicular cliffs of sandstone, lying in horizontal strata. These cliffs however
are in many places interrupted by sandy beaches, behind which the country is low and flat, the high land retiring to a considerable distance. The spaces now occupied by sandy beaches appear at no very remote period to have formed the entrances of bays and arms of the sea. In many places they are now partly filled up, but there still exist extensive salt-water lagoons, separated from the ocean only by a bank of sand, through which the sea yet occasionally forces a passage.

A range of hills north of the Shoalhaven River, which it runs from west to east. It is formed by a remarkable range of high land, which traverses the whole country between the Blue Mountains and the sea, being connected with the former at the source of the Nettai River, and with the latter at Mount Marathon. Of this it must be observed that it extends south-east to the very shores of the sea, between Kiama Head and the mouth of the Shoalhaven River. The highest part is known as the Mittagong Range. The more elevated portion of this tract, which consists of rugged ranges, is a desert, and which and only covered with shrubs. Its southern slope is furrowed by deep ravines, which are hardly accessible except from the Shoalhaven River, into which they open, and on their declivities are only small tracts fit for cultivation, but the soil is poor. Nevertheless, this tract, which along the sea-shore is a lofty range of trap-rocks, called Illawarra, possessing a very rich soil, which in its natural state is buried under matted creepers, ferns, trees, cedar, cabbage-trees, and a luxuriant tropical vegetation, nourished both by the wealth of the soil and the moist sea-breezes, is the southernmost part of the sea. The extent of cultivable ground is small, but it yields most abundantly all kinds of grain and other vegetables. The forests constitute the riches of the settlers in this district. The trees are high and make excellent timber, especially a kind of cedar, of which a great number of boards go to Sydney, though the transport is very expensive, as the country at the back of the Illawarra Range is covered with offsets from the Mittagong Range, which, by their declivity, cause great obstacles to the transport of any heavy article.

From the ravines of the Mittagong Range the country as we proceed northward opens gradually into a kind of plain, the best portion of which is known by the name of the Cow Pastures. This name is derived from a herd of wild cattle which were found pasturing on them when they were discovered. The surface of this plain, which contains upwards of 10,000,000 acres, consists chiefly of undulating thirty-wooded hills, covered with a sward of fine dry native pasture, and with small groves of the most fertile description, producing wheat equaling in quality and quantity the best in England. Some tracts adjoining the river Nepean, which drains this plain, were originally clear of timber; and as they are intersected with ponds and salt-water lakes, which are always considerably flooded after a heavy fall of rain, and consequently make excellent meadows. Cattle abound on this plain, and also sheep; the wool is considered the best in the colony. In the middle of the Cow Pastures is the Raglan Range, an isolated eminence which extends about 8 miles in a general direction between west-north-west and east-south-east; it is very level on some parts of its summit, and so very narrow in others, while the sides also are steep, that the name it has obtained is very appropriate and descriptive.

The Cow Pastures extend over the northern districts of the county of Camden, and the countries contiguous to them on the east and north contain the best portion of Cumberland. The late-mentioned ridge along the sea extends only a few miles inland south of Botany Bay; but between Botany Bay and Port Jackson it reaches the vicinity of Paramatta and Liverpool. The land immediately bordering upon the coast is of a lofty and rugged description, and is frequently sprinkled with stunted bushes. The crops it yields are so scanty, that it would not be cultivated were it not for the vicinity of the capital of the colony. At a distance of from 10 to 15 miles inland the country is somewhat better, and thickly covered with evergreen forest-timber and underwood; but the clayey soil is of indifferent quality, and the labour required for clearing it has been an obstacle to settlements. Beyond this commences the fertile portion of the country, a plain extending from south to north about 40 miles, from Appin on the south to Windsor on the north, with an average width of about 20 miles, so that it is nearly equal in extent to Surrey. The surface of this extensive tract is gently undulating, and rises only in a few places to moderate and isolated hills with a gentle activity. The soil in general is very good, consisting of decomposed vegetable matter, and is underlaid in places by a bed of sandstone, which extends over the declivities of the hills. Prospect Hill, which is the most conspicuous eminence in the country, is cultivated to the summit. Nearly the whole tract could be cultivated with advantage, but it is cultivated only to the limit of the original timber. It is however very generally enclosed by substantial fencing, and affords good pasture for cattle. The rich red soil, derived from the subjacent trap rock, produces crops as abundantly now as when it was first settled, and has a great fertility, with a deep, strong, and brackish, and has a nauseous sweet taste; but in the fresh-water holes it is good, and much relished by the cattle. There seems to be a considerable portion of saline matter in most of the lands of this tract, as it is often seen in dry weather like hoar- frost upon the ground in the vicinity of ponds.

Along the banks of the Hawkesbury are alluvial lands, which exhibit an extraordinary degree of fertility, having yielded one crop of wheat in a few months, and the most of maize in each year for more than 30 years. These lands are exposed to occasional terrible floods, which take place not at certain periods, but irregularly, often after a lapse of many years, and sometimes when the crops are still on the ground. These excesses of water originate in the peculiar nature of the rivers and of the climate. The rivers of this portion of Australia do not run, as in most other countries, in bottoms, but wind in a tortuous course between high grassy banks covered with heavy timber and brushwood. The banks of these rivers are often made to rise to a considerable height above the river, and are frequently isolated by tracts of waste or uninhabited, and sometimes kept so by the natural force of the floods, which are caused by the irregularly rising and falling of the hilly surface of the country in which the upper branches of the Hawkesbury have their origin, the waters are not quickly imbibed by the soil, which consists of indurated clay. They therefore sweep along the surface with irresistible force, and accumulating in the bed of the river, they make it swell with inconceivable rapidity. Its tortuous course, and the fallen trees which are in some parts very numerous, especially where it forces its way through the heavy fall of rain, and is only a few, thickly studded with boulders and rocks, over which only stunted trees are thinly spread. These forests are composed of Bankia and grass trees (zanthorhea), which are usually found in sandy soil where nothing else can grow. These trees always suggest the idea of hopeless sterility. This tract is quite uninhabited, and uninhabitable, even for the aborigines. It is about 25 miles long and 15 wide. It is surrounded on the north-west and north by the Hawkesbury, which flows here in a very deep valley between rocks,
which rise to 600 feet, and are nearly perpendicular; at some places they overhang the river. In this deep chasm the river itself is smooth as a mirror, and affords access by boats and swimmers. The land adjoining is covered by small patches of alluvial soil, which occur alternately on each bank, and comprise farms of from thirty to a hundred acres.

The country north of the Hawkesbury, as far as it is drained by torrents which join that river, is as barren that south of it, but rather more mountainous, and some of the hills rise to a considerable elevation. It is composed of sandstone, a stone which have watercourses from it, except a few isolated heights, which generally consist of trap-rock, and are covered with a tolerably good soil and very heavy timber.

The land is the very lowest part. The alluviums which are drained on the north and south sides of the river, are very much less extensive than those of the Hobartville and Goulburn, and the river has a very different character from that of the Hobartville. The Goulburn flows more or less from west to east, and the Hawkesbury from north to south. The course of the river is so much regulated by the level of the land, that there is a very large difference between the width of the river at different parts of its course.

The land of this district is drained by three great rivers, the Hawkesbury, the Goulburn, and the Liverpool, and a smaller one called the Hawkesbury, which flows from north to south. The Hawkesbury is the most extensive of the three, and has a much larger area of alluviums than the other two. The Goulburn is a very large river, and has a considerable extent of alluviums. The Liverpool is a small river, and has a very limited extent of alluviums. The Hawkesbury is drained by the Goulburn, and the Goulburn is drained by the Liverpool. The Hawkesbury and the Goulburn are both very large rivers, and have a considerable extent of alluviums. The Liverpool is a small river, and has a very limited extent of alluviums. The Hawkesbury is drained by the Goulburn, and the Goulburn is drained by the Liverpool. The Hawkesbury and the Goulburn are both very large rivers, and have a considerable extent of alluviums.
lian Agricultural Company has acquired the property of this
country, it has been ascertained that a considerable portion of
it is not much inferior to the country situated in the
northern portion of Hunter Basin, the bottoms of the rivers
being alluvial, and the higher grounds, which rise only to the
elevation of moderate hills, being clothed with thin
forests and affording tolerable pasture for sheep. The
most southern portion however between Port Stephens and the
Hunter is a low tract, covered with sand, and a useless
waste, a vast expanse of more or less a barren-bar, so that one vehicle
only can enter it: those of larger description are compelled
to anchor outside.

IX. Countries contiguous to the western base of the Blue
Mountains.—Though all the countries lying on the westward
boundaries of the lower counties have been included in our
location, we are very imperfectly acquainted with the fea-
tures and productive powers of a considerable part of
them. The most southern districts, or those which con-
stitute the counties of King and Georgians, are entirely
unknown, as no satisfactory account has been published
respecting them. Mr. Bennett, who traversed a portion of them in his 'Wanderings,' limits his narrat-
tive to a few observations, from which we learn that
despite of the road leading from Sydney to Bathurst and the banks of the river Abereromny
consist mostly of swampy tracts, which are very little available
for the purposes of agriculture or as pasture-grounds.

But south of the river he found the country mostly traversed by
a few wooded, and even level tracts, affording good pasture for sheep, being called open
forests.

The country north of 34° 10' S. lat. is much better
known. A very hilly and broken tract, connected on the east
with the Blue Mountains, stretches for some
miles along the sides of Belubula River. It contains several summits, which rise
to the elevation of mountains, among which the most
elevated is Mount Lachlan, which probably attains 3000 ft.
above the sea-level. This tract at its western extremity
(northward from 34° 30' 33° 30' S. lat.), and separates the affluents of the Ma-
quarie River from those which run westward into the
Lachlan or Calare. Though comparatively narrow, it rises in
some places to a great elevation; the highest of its
summits, Conobals, which is not far from its southern
extremity, attains 4461 feet above the sea-level, and is higher
than the most elevated pinnacle of the Blue Mountains.

The Coutombalas, which are not far from the northern ex-
tremity of this tract, are also elevated, but not so
great a distance. Their elevation has not yet been deter-
mined. Between the southern portion of this western range
and the Blue Mountains are the Plains of Bathurst, which
are twelve miles in length and about five in width. They
are a level tract, tolerably high, not unlike the South
Downs near Brighton, presenting on their surface consid-
erable indurations. The highest parts of these elevations or
knolls are generally covered with deep grasses or bogs, but
otherwise these downs have a dry soil, and are em-
ervatingly destitute of wood, and producing different kinds
of nutritive grass, they afford excellent sheep-walks, but there
are also tracts fit for cattle; the cheese and butter made
here in great request at Sydney. The Plains of Bathurst
are more than 3000 feet above the sea-level.

The remainder of this region, extending northward
on both sides of the Macquarie River, and north-eastward
over the countries lying on the banks of the Cudgee-
gong to the base of the connecting Ridge, exhibits great varieties in its surface and products, and may be said that the
surface is undulating, though the tracts which are farthest from the banks of the rivers
generally rise into hills, which in some places are rather
high. There occur also levels, but they are usually of
short extent, and do not remain long inundated during the
greatest part of the year. The hills in many
places are rocky, and only overgrown with stunted trees,
whilst in others they are covered with grass, and well
though not thickly timbered. Between them are some
narrow valleys, producing abundant pasture for cattle.

At a few places the undulating country is destitute
of water, but these tracts are not of great extent. Many
of the small streams which drain this country are dry in sum-
mer, but well filled after rains. The larger ones have
always water, though it is much reduced after long droughts,
which are frequent in this region. A great portion of
this tract appears to be well adapted for sheep, and this is
proved by the increasing number of sheep-farms which are
spreading over it in all directions. It does not seem
that there is much land fit for growing wheat or other grains;
very little at least has till now been grown, except in Wel-
lington Valley, an extremely fertile tract of alluvial land,
watered by the River Bell, one of the principal tributaries of the
Macquarie. It lies east of the high summits of the Blue
Mountains, and is some 15 miles long, and more than a
mile across where it is widest. In this valley there are
very remarkable caves, in which fossil remains of animals
have been found.

At the distance of about 25 miles from the range on which
the summits of Conobals and Coutombalas stand, is another
tract of heights, which runs nearly parallel to it, along
149° 25' E. long. Its southern portion is called Croker
Range, and its northern Hervey Range. This range has
only been explored at two or three points by Lieut. Colon,
who very imperfectly known. On its western declivity are
the sources of Bogan River, one of the affluents of the
Darling. The country lying east of this range appears, as
far as is known, to have an irregular hilly surface, drained
by numerous watercourses running northwards into the
Macquarie, or southward into the Lachlan; but many of them
are dry in times of drought, or contain only stagnant water
in the deepest depresstions of their beds. Some shee-p-farms
have of late years been established in this hilly tract,
and some small villages have been formed to which the settlements of the whites have extended. On
the west of Croker and Hervey Range begin the great
desolate steppes which extend between the Darling and
Lachlan rivers.

Countries along the Pacific from 32° 26' S. lat.,
or from the mouth of Manning River to Double Island Point.
The Coast Range, or the high land separating the
rivers falling into the Pacific from those running westward into
the great plains of the interior, is probably in most places
from 150 to 300 miles from the sea; it is a very lofty
range, as it has only been minutely examined at two or three
places, it remains uncertain if that range always runs parallel
to the coast, or in some places retreats farther from it. The
cost-line of this tract, extending about 500 miles, is mostly
covered with low and sandy, being broken up at intervals by rocky
points. But in some parts, especially north of Trial Bay
(30° 50' S. lat.) and south of the mouth of Clarence River, are
tracts of coast many miles in length, where it is rocky and
rises to a considerable elevation, but even here no inde-
pendent settlements have occurred, and villages and
harbours are only found at the mouths of the numerous
rivers. The country which lies at the back of this coast
is much more mountainous than that portion of the
country which lies south of Manning River along the Pacific.
Numerous ranges divide and traverse this
range, and traverse the country in several directions.
Their sides are mostly steep and overgrown with thick
forests, which is one of the reasons that has retarded the
exploitation of this country, so that till this day it has
remained unknown, and was only discovered a few years
ago, though some parts of the country have been
penal settlements nearly for 30 years. There are still
some tracts of considerable extent which are blanks on our
maps. The imperfect account we have obtained of these
countries would suggest the idea that by far the greater
part of them is occupied by elevated mountain-ridges. As
far as it is known, the valleys along the rivers are only of
moderate extent, and occupy probably less than one-fourth
of the surface of the country, they rise to a great elevation.
The Three Brothers (31° 49'), only from 3 to 5 miles from the shore,
are visible at a distance of 50 miles at sea. West by north of them is Mount Sea-
View, which is supposed to rise 8000 feet above the sea-level.
Another island to which is attached a very
swampy tract of land, and which rises to more than 4000 feet. Mount Warning, about 12 miles from the
shore, near 28° 25' S. lat, is considered by Minders as the
highest summit visible from the Pacific, and its elevation
is estimated by him at 3300 feet; to the west of it is Mount
Lindesay, rising 7000 feet above the sea level; but the
high rocky masses seem to cover an extensive tract of
country contiguous to the Coast Range, and to be buried by
narrow cliffs, by which the waters collected on the
mountains find their passage to the lower level. This is es-
pecially the case with the country near 31° 3' S. lat., where the
MacLeay River runs for a great distance in a narrow glen whose sides rise 900 feet above its bed; and above this glen it forms two falls, one 235 and the other 150 feet high.

In the narrow valley of the Manning River, which is said to be navigable 20 miles from its mouth, a few settlements have been formed; but at Port Macquarie and on the banks of the Hastings River the population has within a few years so increased, that this district, with the adjacent valleys of the Manning and MacLeay Rivers, have been formed into a county. Port Macquarie is a bar harbour, admirably adapted for ships to anchor. It is a fine anchorage for a great number of vessels. This harbour is formed by an estuary, into which two rivers fall, which however are designed by one name, the Hastings. About three miles of the river is wide and covered with a forest of all the timber however are rather high, but nevertheless subject to sudden inundations. The soil on the margin is generally a rich alluvium, thickly timbered with cedar-trees and matted with vine-brushes, which renders the clearing of the ground laborious and expensive. The large cedar-trees yield good timber, which is shipped to Sydney. The hills surrounding the lower tract are thinly wooded and serve as sheep-walks. This is the most southern district in New South Wales where the sugar cane has been cultivated. The trade with Brazil is carried on regularly. Tobacco is also grown to some extent. Both rivers falling into Port Macquarie are navigable for several miles from their embouchures.

North of Port Macquarie is the valley which is drained by the Barwon River, of the existence of which government was unacquainted up to 1838, though it had for some time before been visited by woodcutters, who obtained excellent cedar-timber there.

The mouth of the river is at Shool Bay, 29° 20' S. lat. The bar of sand at the mouth of the river extends almost two miles; the river rises from a narrow glen, whose sides rise 900 feet above its bed, as already observed. Below this place the river runs through a variety of country, with hills of moderate and considerable height, and gently rising hills covered with open forests and grassy pastures. Several settlements have been made in this tract, and the fertility of the soil is such, that it will probably become a populous district.

The back of the country of the Barwon River, of the existence of which government was unacquainted up to 1838, though it had for some time before been visited by woodcutters, who obtained excellent cedar-timber there.

The country contiguous to the Coast Range, consists of several fine and extensive valleys, separated from each other by narrow rocky ridges, which rise only a few hundred feet above the common level of the country. These ridges are covered with rich cypress-trees of great magnitude. The hills rise with a gentle ascendency, and are covered with open forests; they are equally adapted for cultivation and grazing. The highest hills lie on the north side of the river, where some rises from 700 to 800 feet above sea-level. There are also some parts of this district which are适切身資料。
Plains begins a range of mountains which runs about a hundred miles from south to north, between 31° and 29° 30' S. lat.: it is called Nundawar, or Hardwicke Range, and is a subject of much north of it; it attains a great elevation, some of the summits rising to 3500 and perhaps 4000 feet above the sea-level. The mountainous portion of this chain occupies only from 10 to 12 miles in width, but it is surrounded by hills and offsets, which are the results of the northward retreat of the ranges. A great number of watercourses originate in these ranges, and water the country surrounding it on all sides. Thus the tract of country between the river Gwydir on the east and Nundawar or Peel River on the west, according to its fertility in cattle and sheep, and occupies a considerable portion of land fit for cultivation, though it varies much in its soil. Some parts are barren, and their surface is covered by thick bushes and stunted trees, which prevents the springing up of grass; others are overgrown with forests of small timber, and are supposed to be the most arable; and yet others, which are made of a degree of gluten lighter and sweeter than those prepared from common flour. These plains are only provided with water, as the sandstone of the country and the quality of the soil make it difficult to collect water in springs, which are neither abundant nor of long duration. But after long-continued rains it appears that a considerable portion of the plains is entirely covered with water and contains temporary lakes, but when a drought has continued for some time large rivers dry up, and in their bed are only found pools, generally at considerable distances from one another. In such a state the banks are not at all visible, and the banks are not at all visible, and the water occasionally is not navigable, though in summer it is in danger. The post office at Nundawar, which was established on the 1st of January, 1817, is obliged to return by the immense swamps which he found spreading on both sides of the Lachlan. He travelled in this region for five weeks, through a country over which the waters of the Lachlan were so abundantly dispersed, that the group of swamps admitted the animals to pass, but not the party meet with a dry spot on which to encamp at the close of the day. But when Mitchell traversed it, his party was frequently in danger of perishing from thirst, the river being dried up, and the pools in its bed occurring only at considerable distances from one another. It is possible that along the banks of this river pasture-ground must exist, at least at certain seasons of the year, as a herd of wild cattle was found as far west as 146° E. long., and they must have wandered to this place from the settled parts of the colony.

In reviewing this rapid survey of the soil of New South Wales, we find that between 28° and 30° S. lat., the country which may be considered as available for cultivation or the rearing of cattle and sheep extends to a distance of about 200 miles from the coast line. When we still add the narrower tract which lies between 29° and 28° S. lat., this country covers a surface of more than 100,000 square miles. There are certainly large tracts which must be considered as useless wastes, as the highest part of the country is so covered with boulders as to be unfit for cultivation, and the rest of the country is too poor to be of service for cattle and sheep. If compared with most countries of Europe, it cannot be said that New South Wales is favourable by nature in the fertility of its soil, though the Scandinavian Peninsula and the northern and southern portions of Asia contain certain districts of a much more advantageous proportion. But Europe must be considered as the most fertile portion of the globe, with the exception of the southern and south-eastern portion of Asia. If we compare New South Wales with South America, it is only possible to point out the large country's contiguous tract of equal extent which is superior in fertility. That portion of New South Wales which lies south of 36° S. lat., and farther to the west occupies the whole surface of the country and the course of the river Mulumbidgee, is to all appearance much superior to the old colony in productive power; but as a very large portion of it has not yet been explored, it would be premature to form a decided opinion respecting its value as an agricultural country. It covers an area of more than 100,000 square miles.

Rivers.—The larger river which drains the country between the Pacific and the watershed have water all the year round. They generally flow in beds which are deep and narrow, and are deeply depressed below the common level of the country, and between banks which rise perpendicularly, or nearly
so, from 100 to 200 feet, and frequently higher, so that the streams are inaccessible, except at a few places. This peculiar construction of the channels in which the rivers run renders it impossible to use their water for irrigating the adjacent fields, with any advantages connected with expensive machinery, though certainly great advantages would result from such a practice in a country subject to such long droughts as New South Wales. These rivers are also of little avail as channels for the transport of the produce of the soil. The only means of proceeding on land and water are, according to distance from their mouth, above which their current is frequently broken by rapids and cataracts, which indeed are neither long nor high, but their frequency renders it impossible to navigate them even by small boats.

The Sturt, Sorell, and Shoalhaven rivers are the most considerable of this region, rises on the table-lands east of the Warragong Mountains, and runs about 90 miles northward, measured in a straight line, and then about 40 more miles north by west. Near its banks trees are cut down, and slightly depressed below the general level of the table-lands. In proceeding northward it continually sinks deeper, so that where it forms the boundary between the counties of St. Vincent and Argyll it runs in a cleft 1500 feet deep and between steep rocks furrowed by numerous ravines. Below its great bend the rocks enclosing its bed are less elevated and their acclivities more gentle, but still so close to the water as not to leave a bottom. It emerges from these hills about 20 miles from its mouth, and at this point coming from the south it tap the river from the north, at a yard or perhaps less, as it flows over a ledge of small, rounded, water-worn stones, which are hardly covered with water. The tide flows thus far, and below this rapid the river may be navigated by boats, but its mouth is so obstructed by shoals and sandbanks that it is useless to attempt to use the river for navigation.

The Hawkesbury falls into Broken Bay. It rises, under the name of Wollondilly, on the Connecting Table-lands, and receives nearly all the waters which are collected on them. It flows in a deep bed, which however is accessible. Still it begins to form the boundary between Argyll and Camden, where it sinks into a deep ravine, and is no longer accessible. In this ravine it traverses a country exceedingly wild and broken, belonging to the Blue Mountains, and separates Westmoreland from Camden under the name of Wollondilly and the county of Cook from that of Camden under the name of Warragamba. It issues from the ravine where it begins to form the boundary between Cook and Cumberland, but its current is still so rapid to be navigated. The last rapids occur near Windsor, from which it divides into two channels, one of which is only 40 miles from the sea in a straight line, but 100 at least following the windings of the river, whose waters are fresh for 30 miles below the town. Its estuary, Broken Bay, is the most beautiful and extensive of any in the country, and is navigable for vessels even for large vessels, the best of which is called Pittwater. The whole course of the river exceeds 250 miles. Sometimes the floods of this river rise to 90 feet above its usual level, and the inundations then lay waste the fertile tracts on its banks.

George's River falls into Botany Bay. It runs hardly 60 miles, but is navigable for boats from Liverpool down wards, a distance of about 12 miles in a direct line, but 24 miles following the windings of its course. The water is occasionally brackish at Liverpool in the long summer droughts.

Hunter River disemboages into Port Hunter. It has two great branches, one called Hunter and the other Goulburn. Hunter River originates on the southern de chers of the lagoon, where the chain which is connected with the Coast Range, and flows for about 80 miles south-west in a rather wide valley, which contains a bottom half a mile wide and upwards. Where the Hunter meets the Goulburn, it forms an acute angle, and where the town is, it is called the Maitland River. It is one of the branches of some of the branches of the Brisbane, south of 28° S. lat.; but only a small portion of its course near the mountains is known. It is supposed that it is the same river which, about 200 miles farther to the south-east, is called by Major Mitchell, where it was called by the native Karula. It ran to the west of south, had a considerable body of water, was about 5 feet deep, and was joined by another large river, the Gwyda, which receives the drainage of the countries lying between the Nundawar Range and having alluvial tracts along its banks. Several rivers, running from 50 to 100 miles and upwards, join the Goulburn and Hunter from the north, originating in Liverpool Range. The course of the Hunter is very rapid, which runs for 20 miles in a straight line. The navigation begins at Maitland, about 20 miles from Port Hunter by land, but nearly 40 miles by water, and a steam-boat is now regularly plying between that town and Sydney. This river often rises rapidly after heavy rains, and at such times runs over the whole of its course. The navigable rivers which drain the counties north of the Hunter are the Manning, Hastings, Clarence, and Brisbane, and have been noticed before.

Of the rivers which fall into the southern sea only the Goulburn, or Nangar, need to be mentioned. It rises on the western declivities of the Grampians, flows for more than a hundred miles westward, when by degrees it turns to the south-west, and then suddenly to the south, in which direction it runs about 80 miles. In approaching the sea it turns suddenly westward, and enters Southern Australia, but by another sudden turn to the south-east it returns to New South Wales, where it forms a small basin before it disemboages into the sea. The mouth of this river can never be made available as a harbour. It is bounded on which there are only from one to two feet of water, and on which the sea breaks with great violence; besides, the accumulation of sand is sometimes so great between the east and west shores of the entrance, as completely to obstruct the passage of vessels. The river, as it flows, immediately above its embouchure, has also a depth of not more than two or three feet water: above the basin the river is of considerable depth, and probably navigable to some extent.

The rivers disemboaging into the interior of New South Wales, as far as it is known, appear to belong to one river system, whose basin probably contains an area of not less than 500,000 square miles. It is called the river-basin of the Murray, not from the river which has the longest course, but from the river which carries the largest amount of water. The rivers composing this extensive system may, according to their origin and nature, be divided into three classes. The first class comprehends those which originate in the elevated Coast Range, and receive from it immense supplies of water, and on the other hand, however, they lose by evaporation and absorption in their long course through the arid plains of the interior; so that towards the end of their long course they dwindle down to the size of small rivers, and become fordable. The second class are those rivers which originate on the western declivity of the sandstone rocks of the Blue Mountains, from which they carry off a moderate quantity of water, which after a long-continued drought is so reduced, that it is soon evaporated and absorbed; the beds of the rivers then get dry, and water occurs only in pools or small lakes at great distances from one another. The third class of rivers are those which originate within the extensive mountain-region of the Australian Alps, and in the elevated tracts of country which from this region extends westward to the Grampians. As they are abundantly supplied with water from these high courses, and their course does not lie through desert and arid steppes, at least not to any great extent, they always preserve a considerable volume of water; and many of them will certainly be found fit for navigation in a great part of their course.

The Darling is supposed to receive all the waters which collect on the northern slope of the Liverpool Range and on the western declivity of the Coast Range, so that its upper branches drain the country extending from 32° to 38° S. lat. The most northern of these branches, as far as the mouth of the Gwyda River, is called by Major Mitchell, name of some of the branches of the Brisbane, south of 28° S. lat.; but only a small portion of its course near the mountains is known. It is supposed that it is the same river which, about 200 miles farther to the south-east, is called by Major Mitchell, where it was called by the native Karula. It ran to the west of south, had a considerable body of water, was about 5 feet deep, and was joined by another large river, the Gwyda, which receives the drainage of the countries lying between the Nundawar Range and
the Coast Range. Though the sources of the Gwydir are not known, a part of its course, along the northern side of the Nundawar Range, is known. Farther to the west the course of the Karaula has not been explored, but it is thought to be the same river which was seen by Capt. Sturt between 144° and 147° E. long., and was called by him Darling. He found the water of the river salt at the place where it is joined by the river Castlereagh, which rises in the Liverpool Range, near its western extremity. Nearly all the watercourses originating on the north-west extremity of this range join one another to the south-west of Nundawar Range, where the institute a considerable river, the Peel, or Namnou, whose upper course has been surveyed; but it is uncertain if this river joins the Karaula, or Darling, or if it is lost in an immense swamp. The courses of this river have never been traced. After joining by the Castlereagh, the Darling runs westward through an unknown region, but westward of 146° 20' its course is known. West of 146° it is joined from the south by the Bogan, a river originating in Harvey Range, whose northern extremity of this range joins one another to the west of 146°. The Bogan is joined by the Castlereagh, the Darling runs westward through an unknown region, but westward of 146° 20' its course is known. West of 146° it is joined from the south by the Bogan, its water is found salt by Sturt, and so also lower down; but Mitchell found that this was only the case at some places where there are numerous salt-springs on the banks of the river; the river places its water as quite sweet. At its confluence with the Bogan the Darling runs south-west, and continues in that direction for more than 300 miles, when it turns south, and after a course of 300 miles in that direction, falls into the Murray. In this course the river has been observed to change its course, and is not joined even by a rivulet. It has very little water in dry seasons, and is fordable at most places. Not far from its mouth a portion of its course, about 50 miles in length, has not been explored; but there cannot be any doubt of its identity of the river, as it is supported by the unvaried statement of the aborigines.

The waters descending from the western declivity of the Blue Mountains are collected into two rivers, the Macquarie and the Bogan. The Macquarie originate north of 34° S. lat. Two considerable mountain-streams, the Fish River and the Campbell, unite in the Plains of Bathurst, and form the Macquarie, whose course lies to the north-west; and after a run of about 280 miles it is lost in marshes, which cover a considerable tract of land. In the Plains of Bathurst its surface is more than 1000 feet above the sea-level. After it has passed the northern extremity of Hervey Range it is still 40 yards wide. North of 32° S. lat. it forms a cataract 5 feet high, and at places 650 feet above sea-level. This section of the river is to be a considerable river even in the vicinity of the marshes, where it is from 7 to 10 feet deep. That it preserves such a volume of water is mainly to be attributed to the circumstance that it is joined by two considerable rivers of the same declivity, the Fish and the Campbell. At its confluence with the Bogan in the Liverpool Range, the southern is called Cudgegong, and the northern Erkine River. They fall into the Macquarie before it arrives at Hervey Range. It is supposed that in times of great floods the Macquarie discharges its surplus water either into the Castlereagh by the Morrisett Ponds, or into the Bogan by Duck Creek, channels which at other seasons are entirely dry, or contain only water in a few pools. The Macquarie, or, as it is called by the aborigines, the aborigines, the Culburra, is a river the whole extent of which is not known. It is one of the largest and is still joined by two others, and is of considerable size. In March, 1838: even in the vicinity of the Blue Mountains, where the river is joined by Byrnes Creek (34° 30' S. lat. and 148° 20' E. long.), and farther down, there were only a few small ponds in the deepest part of the bed; but Oxley found in the same season, in 1817, such a volume of water in this river, that he was able to navigate it in a boat. Oxley thought that the Lachlan terminated, like the Macquarie, in extensive marshes; but Mitchell found these marshes quite dry, and ascertained, that when the river is swollen it discharges its waters into the Murray. The numerous rivers which derive their waters from the Australian Alps and the elevated country west of them form the Murray River. This river has two principal branches, the Murrumpurrrrrurrururrum and the Millagro. The Murrumpururrurrurrum, or Murrumbidgee, rises to the east of the Warragong Range, on the elevated table-land contiguous to that chain, and runs for about 100 miles on these table-lands northward, and at the distance of only a few miles from the coast it enters the sea. From the mouth of this river it falls for about 100 miles between high lands and mountains, and then runs westward, until it enters a more level and lower country near 147° 20' E. long. Before it reaches this point the river is joined by three or four tributaries, which drain the north-western portion of the Australian Alps. But below that point it is in its western course joined by no river of any importance until it arrives at the mouth of the Lachlan; but as the last-mentioned river is frequently dry, it can hardly be considered as bringing any supply to the Murray. The distance of the mouth of the Lachlan to this point, probably exceeds 350 miles. After having been joined by the Lachlan it continues to run to the west and south-west for about 100 miles more, when it is joined by the Millagro. The Murrumbidgee is a considerable river, and is not likely to be joined by any of the greater tributaries of this river. It continues, however, its course to nearly 149° W. long., and perhaps higher. Its whole course exceeds 560 miles. The Millagro, which is also called Murray River, receives all the rivers originating in the higher portion of the Australian Alps. They are very numerous, but imperfectly known, except where they join the Millagro. The river has an anchorage at its mouth, and to which the name of Macquarie also has been applied. It is also not known where these rivers form their junctions, as by far the greater part of their course is not known. Mitchell has been here in 1817. The lower course only of the Millagro, for about 50 miles upwards from its confluence with the Murrumbidgee, has been seen by Mitchell. In these parts it is a wide and deep river, flowing through a bottom which is from 6 to 10 miles wide, and running to the north, and is bounded on both sides by high banks. But its vicinity is subject to considerable variation. It is frequently dry, and is often divided into rivulets, and has some ponds. It is also stated to be a place affording safe anchorage.

Climate.—It is evident that in a country which extends...
over twelve degrees of latitude, and borders on boundless steps; the climate must vary considerably. The information we possess of it is very scanty, as been in these parts which have been settled for considerable time. Continuous meteorological observations have not been made, so far as we know. But the few observations that we possess are sufficient to convey a more exact idea of the climate than is usually presented from Port Jackson alone; than the observations of travellers. These travellers however appear not to have been mistaken when they compare the climate of Sydney with that of the southern parts of Italy, as the following table shows, in which the climates of Naples, Sydney, and Paramatta are placed side by side:

<table>
<thead>
<tr>
<th>Month</th>
<th>Naples</th>
<th>Sydney, Paramatta</th>
</tr>
</thead>
<tbody>
<tr>
<td>January</td>
<td>43°-5'</td>
<td>54°-1'</td>

**Mean Annual Temperature.**

<table>
<thead>
<tr>
<th>Month</th>
<th>Sydney, Paramatta</th>
</tr>
</thead>
<tbody>
<tr>
<td>Winter</td>
<td>54°-8</td>
</tr>
<tr>
<td>Spring</td>
<td>56°-5</td>
</tr>
<tr>
<td>Summer</td>
<td>64°-7</td>
</tr>
<tr>
<td>Autumn</td>
<td>66°-8</td>
</tr>
</tbody>
</table>

From this table it appears that the annual temperature of Sydney is about one degree higher than that of Naples, whilst that of Paramatta is higher by one degree and six-tenths. When we consider more closely the details, we find that the heat is more equally divided through the year in the country round Port Jackson than at Naples, as appears from the following table:

<table>
<thead>
<tr>
<th>Month</th>
<th>Sydney, Paramatta</th>
</tr>
</thead>
<tbody>
<tr>
<td>Winter</td>
<td>51°-3</td>
</tr>
<tr>
<td>Spring</td>
<td>56°-3</td>
</tr>
<tr>
<td>Summer</td>
<td>63°-7</td>
</tr>
<tr>
<td>Autumn</td>
<td>66°-5</td>
</tr>
</tbody>
</table>

The cold at Naples in winter is therefore greater than at Sydney by nearly five degrees, but exceeds that of Paramatta only by two degrees. But, on the other hand, the heat in summer at Naples is more than five degrees greater than at Sydney, and more than seven that at Paramatta. This agrees perfectly with the statement of travellers that frost is unknown in the vicinity of Sydney, whilst at Naples it is experienced nearly every winter, and sometimes ice is formed of the thickness of a crown. We find however that at Paramatta the thermometer descends sometimes as low as 27°, and even 20°, whilst in summer it rises to above 100°, and even to 106°. At the same time it is observed that the changes of the weather are frequent, and sometimes sudden at Port Jackson than at Naples, and that the daily and monthly range of the thermometer is much greater, especially in the latter part of the spring and summer, at which season the monthly range amounts to more than fifty degrees. It is even stated that in a very short time the thermometer rises or falls 25 and even 30 degrees. This great and sudden change is produced by the wind turning from north-west to south-east, or rice rised. The north-western winds passing over the heated steps of the southern coast of the Blue Mountains acquire such a degree of heat that they are nearly scorching, and when they immediately set in after a south-east wind, which has brought to Sydney, do not only cool the eastern parts, but even the southern pole, the change is sudden and great. It is stated that in such a case the thermometer has been observed to rise almost instantly from 80° to 110° in the shade.

The annual quantity of rain which falls at Port Jackson has been determined. From the incomplete observations which have been published, it would seem that it amounts to from 36 to 40 inches. The rains are not so between the tropics, limited to certain seasons, but fall all the year round; they are however most frequent in winter (June to August). These rains do not resemble the rains of England, as they fall much larger drops, and are consequently heavier. Thus it happens that though the annual quantity of rain is much larger at Sydney than at London, the number of rainy days is less, by a hundred. Sometimes not a drop of rain falls during five months, but that cannot surprise those who know that this happens also at Naples. The most characteristic peculiarities of the climate of New South Wales are the long droughts which prevail for a portion of the years not a cloud passes over the sky, and the surface of the earth becomes so parched that the minor vegetation ceases to exist. It was supposed that these droughts were periodical, occurring every ten or twelve years. But the long drought which desolated the country in 1822 and 1829 was followed by another in 1833 and 1836, and a still more recent one in 1839. These droughts are generally succeeded by excessively long and heavy rains, which, as is supposed, lay the plains in the interior under water, and change them into temporary lakes. These lakes sometimes continue uninterrupted for a succession of days, without being attacked by thunder or a drop of rain falling.

This account of the climate refers only to the country surrounding Port Jackson. On the Connecting Table-lands and in the Plains of Bathurst, which are more than 2000 feet above the sea-level, the winters are much more severe. Frost is there experienced every night for six weeks or two months, and snow often lies on the summits of the adjacent mountains. It is even found in the valleys and depressions which are not much exposed to the effects of the sun. As in summer, the heat is several degrees less on these elevated counties than at Port Jackson, the grass is not so quickly burnt up, and the rocks of the cliffs find here nearly all the year round sufficient for their sustenance.

We know very little of the climate of the unsettled portions of the colony. Major Mitchell, when traversing the interior on his travels, by the description he made in his journal, by which it appears that while passing through the northern districts, or those which lie at the back of the Coast Range, he experienced in summer, during more than two months, a degree of heat which kept the thermometer on the average at 80° and 90°, and actually forming a circle of desert heat, and it is also stated, but only happened when the sky was for some time overcast or some rain fell. This degree of heat was the effect of the continuance of the north-westery winds, which probably pass over an immense steppe, and are not broken by any ridges of mountains. The climate of this part of New South Wales seems to resemble that of Senegambia. [Vol. xxi. p. 236.] In winter however the temperature appears to be much lower; for in this season the thermometer on the banks of the Darling was found to range commonly between 90° and 100°, and occasionally 106°, whilst in summer, between 80° and 90°, and occasionally 106° and 107°. In Australia Felix, on the banks of the Millewa River, the thermometer varied in winter between 45° and 50°, but in the higher grounds it rose to 70° and more, and descended to 48°. In New South Wales, the thermometer in spring and autumn, is generally between 50° and 60°, and sometimes 60° and 70°, and the nights are often as cold as in England.
Spit, which may be considered as the most southern point of the coral reefs which extend along the eastern coast of Australia from 26° S. lat. to Torres Strait, is an important point for navigators, as at that cape a change takes place in the direction of the winds and currents. No strong current appears to prevail north of that point, but south of it a strong current, running about two miles and a half in an hour, is met with at a distance of 15 or 20 miles from the shore. In summer, between October and February, it carries water to the north and south. In the space between it and the coast there is a weak current, which sets to the north. North of Break-sea Spit the prevailing wind in winter is the north-east trade-wind, which occasionally varies to the south-west coast, and blows with great strength. To the south of Break-sea Spit the winds are more variable, because this part of the coast is without the reach of the trade-winds, and therefore they are much influenced by the direction of the coast, which runs near north and south. Vessels sailing northward in summer accordingly keep close to the shore, where there are no hidden dangers, and where they have in their favour the weak northern current, and may take advantage of the land-winds which usually blow along the coast and may sail through Torres Strait. [Torrres Straits, vol. xxv. p. 52.] But in the opposite season, from March to September, they generally take that route, as at that period of the year the current is in their favour, and the southerly winds blow with great strength. Ships prefer this route, as the navigation through Bass's Strait and round Van Diemen's Land is then very difficult and tedious. For when the sun is in the northern hemisphere the winds, which along the southern coast of Australia generally blow in a south-westerly direction, have great strength in Bass's Strait as if they went through a funnel, and even round the southern part of Tasmania they are so powerful that vessels returning from New South Wales to Europe find it difficult to contend with them, and on this account the return passage through this strait is on an average three times as long as the outward passage. Vessels therefore bound from Sydney to Europe, the Cape, or Hindustan, prefer in this instance to pass through Bass's Strait or round Papua. [Pacific, vol. xvii. p. 118.]

Agriculture and Agricultural Productions.—When the British settled in New South Wales they introduced all the kinds of grain and plants cultivated in England, and in the first few years they added wheat, flax, and tobacco. When they penetrated somewhat farther into the country, where the soil is better than in the immediate vicinity of Port Jackson, the crops, though not very abundant, repaid the labour bestowed on the land, and it seemed to the colonists that the country would turn out a valuable agricultural colony, like Canada. But no sooner had it been ascertained that the soil of the greater portion of the country was much better adapted for pasture, especially for sheep, than the attention of the colonists was almost exclusively directed to that object. This had an immediate effect on landed property: the grants of land which were made in the first 15 or 20 years generally did not exceed 200 acres; but all those which were made at a later period comprehended tracts extending over from 5000 to 10,000 acres. Landed property of small extent is only found in the first-settled counties, especially in Cumberland, and in Camden, Northumberland, and Durham. In the other counties small proprietors are hardly met with. The climate has greatly affected the extension of cultivation; the large proprietors find it most advantageous to convert their large estates into sheep-walks, which, on account of the peculiar nature of the country, can be done without expense; and as they expect to obtain ample returns by the sale of their flock, they do not encourage cultivation, at least not farther than is required for the consumption of their scantily peopled estates. The produce of these cultivated spots is only sufficient for home consumption in good seasons; and in times of drought, the shepherds and other persons attached to the management of the estates must be supplied with grain or bread from other parts of the country and from Sydney. It would even appear that the growth of wheat is on the decrease: we must at least infer it from the data contained in the following table:

<table>

</table>

Though the number of acres under cultivation is small, the produce is considerable, in spite of the careless manner in which it is cultivated. The principal crops are maize or potatoes, or one crop of wheat and another of maize and potatoes, may be taken annually from the same field, if the soil is good and the season favourable. Wheat produces on an average 15 bushels—in better lands even 30 and 40 bushels—per acre; and maize varies from 40 to 90 bushels per acre according to the quality of the soil. Oats are not much grown, except on the high grounds of the Connecting Table-lands and the plains of the Hunter River, where they are used in lieu of maize, which does not succeed so well in these colder tracts. The growth of barley and potatoes is on the increase. Tobacco is only cultivated to some extent on the banks of Hunter River.

The gardens have been at some pains to introduce many kinds of fruit-trees and vegetables, and they have in most cases done it with tolerable success. There are oranges, lemons, citrons, nectarines, apricots, peaches, plums, cherries, figs, quinces, pears, apples, peaches, pomegranates, grapes, raspberries, strawberries, bananas, guavas, pine-apples, gooseberries, and currants; and almonds, walnuts, chestnuts, and filberts. Bananas and guavas come only to perfection in low sheltered places near the sea, and pine-apples require the aid of a frame for filling out and ripening. Gooseberries, on the contrary, succeed only in the colder and more elevated counties, as near Bathurst. Grapes have lately been greatly improved, both as to size and flavour; and as they begin to bear after a great interval, it is hoped that the cultivated vine will constitute an article of export from New South Wales, as the soil seems exceedingly well calculated for the growth of vines.

In the kitchen-gardens are raised melons, water-melons, pumpkins, squash, cucumbers, cabbages, turnips, and other vegetables.

Pastures and Domestic Animals.—New South Wales has become a pastoral country not on account of the richness of its pastures, but because that portion of the country which is fit for that purpose is so extensive. It is asserted, and we think with reason, that the richest swaths there are full two-thirds inferior in point of closeness to the old pastures in England. The grass grows only detached tufts, and between them is so much waste space.
Forests.—The peculiarities by which the botany of New South Wales is distinguished may be seen under AUSTRALIA. In some parts of the colony the trees are useful for domestic purposes, and some of them are of much value. The most valuable is the cedar (Melia azedarach), which is found especially at Illawarra, and on the banks of the Hunter, Hastings, and Clarence Rivers. Several of the trees found in Bass's Strait, as the Eucalyptus, are very valuable, especially the blue gum (Euc. obliqua), the iron bark tree (Euc. resinosa), and the stringy bark tree (Euc. robusta), and from some of these an excellent bark is obtained for tanning, of which small quantities are sent to England. Timber is further obtained from a kind of pine belonging to the genus Callitris. Most of the eucalypt yield a kind of gum, and therefore they have obtained the name of gum-trees. No use has yet been made of this gum, but many think that it may at some future period come to be of value.

A summary account of the zoology of South Wales is found under AUSTRALIA (Vol. iii., p. 126). Several new species of mammals, birds, and fishes have been discovered since that article was written, as a Jerboa dipus, a Choropus ecuadus, &c.; but the best known of all these animals are the kangaroo dogs. A few species of these animals at small numbers, they are not likely to affect the domestic economy of the inhabitants, and are for that reason here omitted. In Bass's Strait and along the eastern coast whales and other cetaceous mammals, and also seals, are very abundant, and the number of vessels belonging to the colony are employed in the fishery.

Minerals.—New South Wales is not rich in metals. There are in some places slight indications of the existence of gold and silver. Iron ore is known to exist in several places, especially on the Black Mountain, in the vicinity of the coal-beds, in Hunter of the Hunter, and in several extensive coal-measures, two of which are worked. Those found near the mouth of the Hunter River, near Newcastle, are extensively worked, and their produce is shipped to Sydney. The coal-beds near Western Port are very large, and those near Port Phillip, on which a very little is yet worked.

An account of their characteristic features is given under AUSTRALIA (Vol. iii., p. 122). It is however stated that their colour is not universally black, but that in the interior, and also at some places on the coast, there are tribes which have a light copper colour, which seems to indicate that they inhabit the south-western or the south-eastern races. Their hair is also not woolly, but only frizzled, and never grows long.

Though dispersed over such a large extent of country, it does not appear that the different dialects spoken by them are so widely different as to render the aid of an interpreter necessary for the purpose of communicating with one another. Mitchell, having collected vocabularies from different parts of Australia, finds that in the languages of those tribes which inhabit the south-western and the south-eastern races of that continent several words are found, mostly applying to different parts of the human body, which are either the same or resemble one another greatly, whilst no such resemblance occurs between these words and another tribe, the language spoken by the natives on the northern coast of Australia.
The aborigines certainly live in a very low state of civilization. This is proved by their going almost naked. The men wear girdles, usually made of the wool of the opossum; and a sort of tail of the same material is appended to this girdle, both before and behind, and seems to be the only part of their costume suggested by any idea of decency. Rouse the men in possession of a neatly-wrought bandage or fillet, which they whiten with pipe-clay, as a soldier cleans his belts. They also wear one of a red colour under it. The women generally wrap themselves up in a species of cloth made of the blackbuck and blesbuck. As some of these tribes live in parts which are subject to a considerable degree of cold in winter, it is rather a matter of surprise that they have not adopted a warmer clothing. But they generally pass the nights bare-headed.

As most of the tribes are continually moving about in search of food, they have no fixed abodes. In the night-time they protect their fires by the bark or the boughs of a tree placed to the windward. A few tribes however living along the coast of the Pacific have fixed habitations. In 1839, when the newly discovered Clarence River was explored, a number of huts, forming a temporary village, was found at the head of a deep estuary which appeared to give a considerable command of fishing-ground. This small industry is of considerable value in the manufacture of their utensils and arms. Mitchell found that the nabs used by the aborigines on the large rivers of the interior approached nearer to those made in Europe than any other thing made by them. The fishing tribe on the Clarence were possessed of nets, fish-baskets, skin vessels, and cooking utensils, which were made with peculiar care and neatness. The same observation is made respecting their arms, of which that peculiar kind of missile called domoring is attached to the headdress of all travellers, as it is used in a very unusual way. A description of it and its uses is found in Mitchell's 'Three Expeditions,' &c., vol. ii., p. 348.

The opossums constitute the ordinary food of the nation, and are the basis of all their other manufactures. They are the work of the forest, and seem to be to a great extent adapted to the climate. The animals are always very fat, and easily procured. As the skin is soft and shrivelled, and of such a length and breadth as to be very useful, the men have made of it many articles.

The natives are accused of cannibalism. Mitchell, who certainly knows them well, denies the fact. But Bennet heard of a weak and sickly child having been destroyed, and even eaten. This appears however to have been an exceptional case. In another instance, the parent was so very hungry, and the child was of no use and much trouble. Infanticide however is not rare, and the alleged reason is that the children are too much trouble to carry along, and that the parent almost starved to death destroy the infants produced by the intercourse with Europeans, unless the father resides constantly with the female, or may be near her at the time of the birth to prevent it. The most remarkable of their customs is the practice of striking out one of the front teeth of the males at the age of puberty, and that of the females of cutting off the last joint of the little finger.

The aborigines have frequently attacked remote stations, and killed the settlers. This is partly attributed to the harsh and unjust treatment they have experienced from the hands of convict-settlers, or convict-servants, and partly to the desire of appropriating to themselves some portion of their property which they think useful. Besides, it is observed that when a white man has been killed by them, it is the custom to return to punish with the whites, until one of their tribes has been killed by the whites. This appears to originate in the principle that bloodshed can only be atoned for by the shedding of blood. From time to time they have in different parts of the colony carried off white persons; but as they do not take their outrages very seriously, it has been obliged to send the police force against them, and to attack them regularly, until they are impressed with the superiority of the whites; when that has been done, they no longer molest the settlers.

The aborigines are of a more advanced state of civilization than most of the native tribes of America. Mitchell speaks highly of their mental powers and judgment in everything they are acquainted with. He thinks them in man-
westerly of the Coast Range lying at the back of Moreton Bay; and this part of the interior is now known by the name of New England. In Australia Felix the stations extend to the vicinity of the Nangarri River, not far from the boundary-line of South Australia, and along the coast beyond Port Phillip.

The number of licensed stations amounted, in 1839, to 699. The number of stock for which assessment was paid was 7068 horses, 371,699 horned cattle, and 1,334,313 sheep. The real amount of livestock however, probably considerably exceeds the amount returned.

But it is thought that these stations have now attained the extreme limits to which they can extend. Their distance from Sydney is now so great, that the feeding of sheep and beef destined for profitable export must at present be beyond wool being the expense of transport to such a great distance. Government has therefore lately resolved to open roads to some other harbours which are much nearer, and on which there have hitherto been no settlements, or at least easily accessible of arable lands such as the countries west of the Coast Range to the ports of Moreton Bay, Shoal Bay, or the mouth of Clarence River, and to Port Macquarie. South of the boundary of location, roads are to be made to Twofold Bay and Portland Bay. As the transport of goods will be much extended to these places, and the expenses consequently diminished, it is hoped that the stations will continue to extend farther to the west and north.

Some two years ago a road was opened from the connecting Table-lands and the banks of the Murrambridge to Port Phillip, which runs through a country which only eight years ago (1830) was traversed for the first time by Europeans, and along which there are now a considerable number of stations, and also inns at convenient distances.

There is no want of roads within the boundary of location. Three lines of roads, which have been made at considerable expense, traverse these countries. One leads from Sydney on the new main line, to a branch of the Nepean, another to Hunter River, and a third to the fine pastoral countries on the connecting Table-lands. These roads are not inferior to any on the continent of Europe, and nearly equal to those of England: but as they all terminate at Sydney, the sense of transporting the produce of the land from the southern districts is considerable, and operates as a check on the industry of the inhabitants. But a new line of roads is to be opened from the connecting Table-lands to Jervis Bay, nearly 100 miles south of Sydney, by which the distance from Port Jackson and the market will be shortened by more than one-half for these districts.

Inhabitants.—The white population of New South Wales consists of two classes, freemen and bondmen. The former are of English extraction and were transported from Great Britain to that country as a punishment for their crimes. As New South Wales in the beginning was merely a penal settlement, its population was far more than twenty years after the foundation of the colony at least as large as the number of convicts transported on the establishment of the colony. The number of convicts has been less than the amount of population. Even after the colony had been opened to free immigration, the circumstance that its inhabitants were only convicts deterred many persons from going to settle there; and up to 1830 the number of free immigrants was very small in comparison with those who went to Canada and other colonies. The census of 1831 gave 46,276 inhabitants, and that of 1841 amounted to 130,856; so that in the last ten years the population has nearly doubled itself. It would soon come to one in five if the character of the colony having gradually changed from a penal settlement to an agricultural settlement, which offers great advantages to an industrious man, and in which he can now enjoy the fruits of his industry without fear of being stripped; and up to 1830 the number of free immigrants was very small in comparison with those who went to Canada and other colonies.

But New South Wales still continues to be a penal settlement. The number of convicts annually sent to that colony is still considerable, and exceeded, up to 1830, that of the free immigrants, as is evident from the annexed table:

The convicts are divided into three classes. The worst characters remain under the immediate surveillance of the inhabitants, of whom, and the employment of, government, which occupies them erecting public buildings, making roads, building bridges, &c. A considerable number is assigned to private persons, who either send them to their estates to serve as agricultural labourers, shepherds, &c., or employ them as criminal servants. The freed convict in the state of assignment has escaped punishment for four years he receives a ticket-of-leave, if he has been transported for seven years; but if he has been transported for fourteen, he must have undergone punishment for six years, and to be the condition of life, not for eight years, in order to obtain a ticket-of-leave. Those who have tickets-of-leave constitute the third class of convicts, and they are free to a certain degree, as they may employ their time as they think it most advantageous to themselves; but they are divided into two classes, one inhabiting the districts which have been assigned for their residence. Those who have passed in the colony the whole time awarded by the sentence of the criminal court, may return to England or any other country, or remain in the colony, which the number of the different classes is determined with great care by the government.

That the annual introduction of such a number of convicts must lower, or rather keep down, the moral condition of the inhabitants, is evident, and the experiment of discharging them from the colony as a penal settlement has repeatedly been suggested. This change has been insisted on still more in a political view. In present circumstances it is not advisable to grant to the colony a representation. The two parties, the free settlers, the free convicts, the free immigrants, and the free agricultural labourers, have the same interests, and therefore only desire the same objects. The great number of convicts retards the progress of the colony. They are considered by free inhabitants nearly in the same light as the negro slave population in the southern parts of the United States. The free convicts evince a great aversion to undertaking such kinds of labours and services as are commonly performed by convicts, and thus the most necessary labour in the cultivation of the ground is done in the most negligent way, a very small number of the convicts having been brought up as agricultural labourers. The discontinuance of sending convicts to the colony would probably also lead by degrees to the civilization of the aborigines. They show, as we have observed, no aversion to taking care of flocks, and there is no part of the country where the assistance of shepherds with a good deal of care and attention. If the proprietors of the sheep-stations, which are so numerous, could not be assisted by the convicts, they would be obliged to engage young native blacks for that purpose, and if they would pay five pounds a year, a very considerable amount, which will enable them to take care of their wandering life and to fix themselves in the midst of the white inhabitants. This course of events must soon lead to other more important steps, and the conversion to Christianity could easily be effected.

Population.—The last census was taken on the 2nd of March, 1841, and its results are laid down in the following tables. The districts to the proper names of which an asterisk (*) is prefixed, are Commissioner Districts beyond the boundaries of location.

| Total                 | 8274  | 4946    | 13220        |

Both portions of the colony, inclusive of Norfolk Island, contain, according to this census, 128,720 inhabitants: but it was considered that at the time of the census 20,000 persons were absent from the country in vessels belonging to the colony, most of them engaged in the whale and seal fishery. Thus the whole population of the colony amounted to 148,720 individuals.

The wealth of the colony is very unequally distributed over the surface of the colony. Nearly one-half of it is settled in the county of Cumberland, or rather in two-thirds of that county, as the most northern districts are a barren waste, and contain only a small number of cultivable acres along the banks of the Hawkesbury River. Northumberland stands next to Cumberland in population, containing nearly 10,000 inhabitants, who are almost exclusively settled on the fertile tract along the Hunter River and the alluvial valleys of its tributaries. The towns contain more that half the population, but the care also more than half the land which is under cultivation in the colony, for in 1837 the land cultivated for grain in the colony consisted of 8,424 acres, and of this number 26,726 acres were within Cumberland and 22,952 within Northumberland. This is not to be attributed exclusively to the superior fertility of these counties, though indeed the soil of most of the surrounding counties is inferior quality, but more especially to the state of landed property. With a few exceptions, all the small proprietors are found and land in these two counties, and in those of Camden and Durham. The number of landed proprietors, merchants, bankers, and professional persons amounted, in 1841, in the whole colony, to 4477, inclusive of the towns. Of this number 1896 resided in Cumberland, 423 in Northumberland, 430 in Camden, and 225 in Durham. Thus we find that nearly two-thirds of the above-named classes of persons were found in these four counties, and if those who reside in the towns are subtracted, it is very probable that one-half of the landed proprietors are found in them. From this the more the less the risk of any centralization in the other counties and districts the population is composed, almost entirely of shepherds and other persons employed in the care of sheep, a small number of people employed in agriculture, and a few mechanics and retail dealers. The increase in the population of the city is due to immigration. The disparity of the sexes is so great, that were the country left to its own resources, many years would certainly pass until such an equality would be established between them. The females stand to the males at present as one to two. This misproportion is chiefly produced by the number of male convicts and male emancipists, which exceeds about seven times that of the females of the same class. Among the landed property the difference in the number of the sexes does not amount to much more than one-sixth part of the whole. The immigration however in what may be called the Old Colony, that is, that portion which lies between 30° and 32° S. lat., will, we apprehend, be being still checked by the value of property. Few tracts of land, except such as are quite barren and hardly worth possessing, and a considerable number of town allotments, are at the disposal of government. The large landed proprietors expect the return of their outlay from the purchase of their flocks of sheep. It was their object to sacrifice a part of their present income to the prospect of an increase at a distant period, by converting a portion of the pasture into cultivated fields. They are still less inclined to sell such tracts as are fit for cultivation to the immigrants of the latter generation, and to the expectation of acquiring landed property and are disinclined to take lands on lease. It appears also that in the countries lying at a moderate distance from the sea little good land is to be found, except what has long ago been brought under cultivation. Not more than twenty years have passed since the establishment of the Australian Agricultural Company, which then acquired a tract of 437,000 acres in the country between the Hunter and Manning Rivers, and it still does not appear to be considered by farmers, agriculturists, shepherds, mechanics, &c., and now we find, after a lapse of 20 years, that the whole population of the county of Gloucester, in which these grants are situated, amounts only to 1426 individuals, though it has the immediate advantage of being situated near the mouth of a harbour which offers safety to coasting vessels.

The emigration will probably, for a considerable time to come, be directed to those countries which are north of 32°, but more especially to Australia Felix, or that part which extends from 32° south to 40°, as the latter appears to be in a much larger proportion of arable land than the Old Colony. The rapid rise of the colony of Port Phillip is almost unprecedented. It was regularly founded by Sir Richard Bourke in 1803. Before that time, however, the town of Port Phillip was established at Western Port and Port Phillip, and they were small and contained only a few inhabitants. The census of 1841, taken only four years after the establishment of the colony, gives it a population of 11,738 individuals. When it is considered that the colony at Port Jackson two years after its foundation contained only 10,000 inhabitants, this rapid increase of the population in the new colony augurs very much in favour of its superior soil and situation. It would however appear that in this new colony government has not taken such care as in the old, which are fit for cultivation, together with such lands as are for the present only to be used as pasture-grounds, but it reserves lands of the first description for the emigrants, and only expects to flock in preference to this country, which is so much more favourably situated by nature in almost every respect.

Education.—There are three colleges, or grammar-schools: two at Sydney, called Sydney College and Australian College, of which the former was attended by 135 students in 1838, but the number which attends Australian College is not stated. King's School, at Parramatta, was attended by 105 students in 1838. These high schools are supported by the payments of the students. The elementary schools are mostly maintained by government. In 1838 there were thirty-five schools, belonging to the church of
England, attended by 2468 children, 1396 boys and 1072 girls. The number of schools for the children of the Roman Catholics amounted to twelve, and were attended by 953 children, 473 boys and 382 girls. These schools were entirely supported by government, which amounted to more than 10,000L. Besides there were in the same year seventeen schools belonging to the Presbyterian; and six others belonging to other denominations of Christians. Government contributed to their support 1276L. and 210L. in kind, which was supplied by private contributions. The number of children attending these schools is stated in an unsatisfactory way. The number of private schools was sixty-seven. They were attended by 1860 children, of whom 932 were boys and 928 girls. The Atlantic and Indiaman are到来 the town of Sydney, 1700 miles away. These were hardly inhabited villages in England. They are most numerous in the most populous portion of the colony, in Cumberland.

Paramatta, or Parramatta, is built on the innermost recess of Port Jackson, in a hollow surrounded by rising grounds. The stipulation required not exceed 800 individuals, west, and north and south, but are neither paved nor lighted. The houses are unconnected, being generally detached cottages partly surrounded by gardens. A considerable number of them are of two stories, and many are brick or white freestone, and all roofed with iron-bark shingles. In this town is an observatory, erected by Sir Thomas Brisbane. The population probably exceeds 4000 individuals. It derives its import from the retail trade, and is chiefly clothed with homespun. In the country which extends along both sides of the river above the town have raised it to a commercial place, as considerable quantities of grain are shipped in this town. There are at Windsor five mills for grinding grain, two for hemp, and four tanneries. The retail trade, and the considerable retail trade, as the country south of it is the most fertile and best cultivated tract in Cumberland, the banks of the Hawkesbury excepted. South of Liverpool is Campbell-town, with about 400 inhabitants, some totaling and two tanneries.

Newcastle is built at the mouth of the Hunter River, which forms a harbour deep enough for merchant vessels, but the entrance is so narrow and crooked that it is dangerous for any vessels except schooners or cutters to work in and out. The town is built on the declivity of a hill of moderate elevation, which is united to the mainland by a low swampy neck of ground. About fifteen years ago it was a thriving place, but since the foundation of Maitland, and the establishment of a regular communication by steam-boats between this town and Sydney, it has lost its commercial importance, which now rests entirely on the coal-mines in its vicinity, which however are worked to some extent. Maitland is built on the southern banks of the Hunter, 40 miles from the mouth of the river, and on the plains, consisting of butts, and is irregularly built. It derives its importance from the extensive plains in which it lies and the excellent pasturage which these plains afford.

In the lately established colony of Port Phillip is Melbourne, built on the northern recess of the extensive bay called Port Phillip, and at the confluence of two rivers, the Marribumong and Yarra Yarra, each of which is navigable for small sea-faring vessels for several miles from its mouth. The town is only in its very infancy, but as the county of Bonke, in which it is situated, only four years after having been settled had risen in population to be the third of the whole colony, being on an inferior to Cumberland and Northumberland, it bids fair to outstrip in importance and size, in a comparatively short time, even Sydney, and may eventually become the capital of our settlements in that part of the world. The greatest advantage does not seem to be derived from its being built in a very fertile tract of land, but from its situation to the west of the western entrance of Bass's Strait. This may be considered as being a month's sail nearer to the countries lying to the west of the Atlantic and India than the Ocean that lies along as the sun is in the northern hemisphere, when the winds blow through Bass's Strait and round Tasmania with such force that it is almost impossible to stem them. Vessels departing from Melbourne may sail to the East Indies, the Cape, and Europe, all the year round, without being obliged to attempt the dangerous passage through Torres Strait. This circumstance will probably in a short time secure to this new town a superiority over Sydney. But the same advantages is also possessed by the town of Geelong in the county of Grant, which is built at the innermost recess of Geelong Bay, the most western portion of Port Phillip. A new town has lately been founded in Portland Bay.

Industry.—The manufacturing industry of the colony is still in its infancy. The most numerous manufacturing establishments are the mills for grinding and dressing corn, turned by wind, water, horses, or steam. In 1836 there were 85 of them in different parts of the country; 17 were at Sydney, which have been increased to 25. There are also a few of soap and candles, and a few distilleries and breweries; but all on a small scale. Common earthenware is made to a considerable extent not far from Sydney.

Two branches of industry however are carried on to some extent, the fisheries and the building of vessels. As a large number of spermaceti-whales and seals, which freest to the sea adjacent to the eastern entrance of Bass's Strait and the Strait itself, and a great number of seals are found on the islands in the same part of the sea, the whale and sea industry has an increasing number of gain to the colonists, and is carried on to some extent.

Vessels engaged in the Fishery, and their Produce.

As several of the forest-trees of New South Wales afford timber, and some of large dimensions of export, to the lately been set on foot. The vessels however are only of moderate size, the largest not exceeding 80 tons burthen. In 1837 the number built was 17, and their burthen 700 tons, and in 1838 there were built 20 vessels, with 808 tons burthen.

Commerce.—New South Wales, considered as a commercial country, holds a very high rank among our colonies, if its scanty population is taken into account. It is true that the value of its imports falls considerably short of that of our colonies in the West Indies, but they are supplied with colonial articles of consumption. It cannot be compared with that of Guyana, or of Jamaica, Trinidad, and the other islands of the West Indies. But in these colonies cultivation and commerce are unlimited, and the produce is calculated for a foreign market, and the population is in a general measure supplied with food and clothing by importation from foreign countries. As this is not the case in New South Wales, this colony, as far as regards commerce, is rather to be compared with those colonies which are in a similar condition, and in this point of view it makes a very conspicuous figure. The Canadians, with nearly a million of inhabitants, exported in 1837 only to the value of 26,707L., whilst New South Wales, with less than 120,000 inhabitants, yielded articles of export to the amount of 788,940L. In the same year the Cape, with
a population of nearly 250,000 individuals, exported only to the value of 281,385L. Tasmania is to be ranged with New South Wales, having in 1837, exported the value of 366,703L., or upwards of 80,000L. more than the Cape, though its population in that year hardly exceeded 45,000, amounting to only one-fifth of that of the last-mentioned colony. South Wales and Tasmania, are to be considered, in a commercial point of view, as intermediate between the tropical colonies in the West Indies and our other colonies which in cultivation and productions more resemble England. They have this advantage to the peculiar dryness of their climate and soil, by which they are rendered more fit for the rearing of sheep than any other part of the globe. As the principal article of export in both the colonies is wool, and as by far the largest manufacturer in which wool is consumed, is the commerce of both colonies is almost entirely limited to England and to those of its colonies by which they are supplied with such articles as are required for their consumption.

**Total value of the articles imported from other countries and re-exported** £90,504

The total value of exports amounted to 768,940L., that of the imports exceeded nearly by 100,000L., as it amounted to 864,255L. The difference between the imports and exports appears chiefly to have arisen from the imports of produce and manufactures, which were 4,253L. in number. The most important articles of importation were manufactured goods, as cotton manufactures, 68,740L.; silk manufactures, 32,266L.; woollen manufactures, 49,433L.; linen manufactures, 28,910L.; and apparel and slops, 68,950L. Other larger articles were tea, £27,134; and sugar, £16,818L., of which £284L. consisted of all sorts, 26,367L.; spirits, 21,000L.; beer and ale, 24,914L.; glass, 23,164L.; haberdashery, 34,893L.; hardware and cutlery, 22,310L.; iron in bars or pigs, 11,350L.; wrought-iron, 22,121L.; leather manufactures, 28,987L.; vessels, 17,097L., book paper, 12,728L.; and books, 12,289L.

In 1838 the colony possessed 41 vessels, of 6,229 tons, which were partly employed in the coasting trade, and partly in the fisheries. A steam-boat plied alternately between Sydney and Paramatta, and between Sydney and Maitland on Hunter River.

**Government.**—The colony is administered by a governor with the assistance of two councils. The council is called the Executive and the Legislative. The Executive is composed of official members, and the governor is obliged to consult it on occasions of any moment; but he is still authorized to act on his own responsibility, provided he states the reasons for so doing, and the reasons for not acting, when he frees himself from the control of the council. The members of the legislative council are not chosen by the inhabitants, but appointed by government, and consist partly of officers of government, and partly of landholders and merchants, with the chief-justice as president. He is authorized to impose taxes or to pass laws for the benefit of the colony, provided those laws are certified by the chief-justice to be conformable in spirit to those of England. The governor has the initiative of these laws. If the two councils are opposed to any act proposed by him, it cannot pass; and in that case the reasons of dissent are entered. The chief-justice, being authorized to declare whether the proposed law is or is not conformable to the laws of England, is considered as having a veto. Laws passed by the legislative council must within seven days be enrolled in the Supreme Court, and fourteen days after such enrolment they come into operation. The assemblies existing between the immigrants and their descendants on one side, and between the emancipists and their offspring on the other, seems to be a sufficient reason for withholding from the colony the boon of a free legislative body.

The judicature consists of a Supreme Court, composed of a chief-justice and two resident judges, with quarter-sessions, and courts of requests, which last have jurisdiction in matters of the extent of ten pounds.

Civil cases are tried by one of the judges, assisted by two magisterial assessors, if both parties do not agree to a trial. If there is a disagreement, the judge has a casting vote. Criminal offences are tried in the Supreme Court by seven military officers as a jury. The magistrates of the thirty districts into which the colony is divided sit daily for the trial of petty offences; their decision is finally subject to the appeal of the governor, who is advised by the chief police magistrate. These magistrates have at their disposal a large constabulary force, composed mostly of convicts, and a few of the native blacks.

**History.**—Though the western and northern coasts of Australia had been discovered by several Dutch navigators during the seventeenth century, that portion which at present constitutes the colony of New South Wales was
unknown up to 1770, when it was discovered by James Cook in his first voyage, and received him his present name. The southern parts of the coast however remained unknown up to the end of the last century, and up to that period it was thought that Tasmanias, which had been discovered by Tasman, was land westward into the interior of Australia. The part or that which lies on both sides of Portland Bay, was first seen in 1802 by the Frenchman Baudin, who had been sent, after the peace of Amiens, with some vessels to make discoveries in the Pacific, and it was soon afterwards surveyed.

The reasons which induced the British government to settle a colony on this coast, and the reasons which determined Governor Phillip to give a preference to Port Jackson above Botany Bay, have been mentioned in the article by that name. As it was soon after ascertain- tainly be called a happy one, as it is now known that at no other place along the coast is such a large tract of fertile land found, at no great distance from the sea, as west of Port Jackson, with the exception of Port Phillip. But even with this fertile tract the progress of the colony was slow in the beginning, which was owing to the circumstance that the first settlers were only convicts. It was not until some persons connected with the govern- ment, and others were salted, that they began to cultivate several tracts of land with success, that the colony began slowly to rise in the esteem of the public. How slow the progress of the colony then was, may be inferred from the circumstance that its population in 1810 did not exceed 10,000 individuals. It was about this time that one of the landed proprietors ascertained that the climate and soil of the colony were very favourable to the rearing of sheep, and as soon as that became known, many persons went to the colony to settle there. But they soon found out that land had been granted away, and that there was no floor space between Port Jackson and the Blue Mountains, was settled, or at least had been granted away, and it appeared impossible to extend the settlements farther westward, as several at- tempts to pass over the Blue Mountains had been frustra- ted. In 1813, when the colonists were visited by a most distress- ing season of drought, three enterprising individuals, Blax- land, Lachlan, and W. G. Leura, undertook the conquest of the mountains. They effected it by never descending into any of the ravines after having attained the upper part of the range, but by keeping on the high ground form- ing the separation of the innermost recesses of the ravines, which so much abound in the country. In 1825-26, the Kurrara, a large river of the south-western point of the colonists, and in the same year followed the discovery of that fine pastoral country the Downs of Bathurst. In the following year a practica- ble line of road was constructed over the mountain-ranges by the persevering efforts of the three enter- prisers, so that two of the rivers draining the Downs of Bathurst ran off in different directions, the government of the colony thought it incumbent on them to set on foot an expedition to explore the whole of the interior. Of the three, Mr. G. Leura, the surveyor-general of the colony, undertook the task in 1817. He first descended the southern river, the Lachlan, and after having traversed a great extent of arid plains, not un- like the steppes of Central Asia, he found that the river terminated in a swamp opposite the adjacent hill grounds, and ter- minated in extensive morasses, which were west of 140° E. long. In following the course of the Macquarie, after traversing arid plains, he also arrived at extensive marshes, in which the river terminated. As the two largest rivers then known had traced out, with the assistance of the surveyors, the northward course of the Macquarie, Oxley went eastward, passed over the Liver- pool Plains, which are still more extensive than Bathurst Downs, and reached the sea at Port Macquarie. Since this period, nearly every year some portion of the country has been discovered and explored. In 1819 the woody country separating the Cow Pastures from the connecting Table- land was penetrated, and Goulburn Plains, and soon afterwards Moneroo Plains, were discovered, and here the Mur- rumridge River was found, which, it was soon ascertained, emptied itself into the interior of Australia. In 1823 Hovell and Hume, two enterprising agriculturists, penetrated from Goulburn Plains in a south-westerly direction into that portion of the continent which now is called Australia Felix, and arrived at Port Phillip. In 1827 Allan Macquarie, who had been sent by government to explore a country lying to the west of the Coast Range, north of Liver- pool Plains and Port Macquarie, and he succeeded in traversing a tract extending over four degrees of latitude, which had never been seen by Europeans. He termin- ated his journey at the head of a large river, which was later known as the Macquarie. Oxley and his party had been known for twelve years, as it drains the Plains of the Connect- ing Table-lands, whence it descends to the west. He traced the river down its right bank until he had passed every rapid and waterfall, and he then launched a boat which he had conveyed overland from Sydney, and descended the river to its confluence with the Millewa, where he entered the Murray. He pursued his course on the Murray, passed the mouth of the Darling, and followed the river to its mouth. In his report he refers to the discovery of a very large river, which according to his account was called Kinrara, and drained an immense tract of fertile country about 300 miles north of Liverpool Plains. The place was sent for, but no steps were taken to follow up this report. In this journey he traversed the hilly country east of Liverpool Plains, and farther north the fertile tract lying west of the Harwich or Nundawar Range, and arrived at last in 70° S. lat., at a considerable distance from the capital of the colony. The Murray was sent for, but no steps were taken to follow up the discovery of this river. In his third expedition (1836) Mitchell descended along the course of the Lachlan, and found its bed everywhere the most extensive morasses, which had prevented Oxley (in 1817) from extending his expedition farther westward. He traced the bed of the Lachlan to the place where it discharges in rainy season the surplus of its waters into the Murray, the drainage area of which includes the lower part of the course of the Darling, he passed to the country south of the Murray River, traced the lower course of its great branch, the Millewà, to its confluence with the Bayang, and a part of the last-mentioned river; and then, by the north coast, and by the route to the south-west, he passed round the northern extremity of the Grampians, and descended from the higher grounds to the sea along the course of the Nangeela. From Portland Bay he returned to the colony by travelling across the highlands in which the river rises, and by the route to the northward to the Murray River. He called this country Australia Felix, on account of its superior fertility and abundance of permanent streams. The discovery of this part of the country and the infor-
WAL 24 WAL

publication obtained respecting the fertile tracts of land which surround the excellent bay called Port Phillip, determined the government, Sir Thomas Bourke, to plant, in 1837, the New Colony at that place, and to found the town of Melbourne. The rapid rise of this colony has led to a closer examination of the surrounding country. Mr. Tyers surveyed, in 1839, the plain which lies to the south of Port Phillip extends westward to the boundary-line of South Australia; and Count Strelecki, a Polish refugee living at Sydney, traversed, in 1839, the interior of the mountain-region of the Australian Alps, ascended the high summit of Mount Kosciusko, determined the true latitude of the summit, and described the coast and the interior of that land, and from that place to Melbourne. But only a small portion of the country surrounding Port Phillip has been explored by these expeditions. It can however hardly be doubted, that in a few years this region will be known as well as the countries lying to the south, west, and north of Port Jackson.

WAL 24 WAL

Wales, William, an English mathematician and astronomer, was born about the year 1734, of parents in humble circumstances. It is not known in what manner he received the rudiments of education, and it is probable that he was one of the many persons who, for their attainments in science, owe more to nature and intense application than to the precepts of a teacher.

He first distinguished himself as a contributor to the Ladies' Diary, a work containing an extensive collection of astronomical and mathematical solutions, which was begun in the year 1704; and under the able direction of Brightton, Thomas Simpson, and Dr. Charles Hutton, it had no small influence in promoting the advancement of science in this country during the eighteenth century: it must, however, be observed, that it is no longer a period of the century, by several eminent mathematicians. Many of the solutions which were given by Mr. Wales are signed with his own name, but occasionally they appear under fictitious signatures.

The merit shown in these solutions appears to have procured for him a recommendation to the government; and in 1788 he was appointed, together with Mr. Dymond, to go to Hudson's Bay, for the purpose of observing in that region the transit of Venus over our sun's disc, which was to take place in the following year (June, 1789). The observations were made at Fort Prince of Wales, and each of the observers was so fortunate as to witness the exterior and interior contact at both the commencement and end of the eclipse. Moreover, Mr. Wales made a number of astronomical observations, an account of which was published in the Philosophical Transactions for 1789; and again, in 1772, in a separate work, entitled General Observations made at Hudson's Bay, &c., Lon- don. He also, principally, subscribed for the observa-

WAL 24 WAL

Mr. Wales returned to England in 1770, and in 1772 he published 'The two books of Apollonius concerning Determinate Sections,' London, 4to. In the same year he was appointed, together with Mr. Bayly, and with the title of astronomer, to accompany Captain Cook in his second voyage for the circumnavigation of the earth; and on the return of the expedition he was, in 1776, elected a fellow of the Royal Society. A series of astronomical observations which had been made during the voyage, with an introduction by Wales, was published in 1777, at the expense of the Board of Longitude, in a quarto volume, with charts and plates. Mr. Wales's 'A tract entitled Observations on a Voyage with Captain Cook,' and, in 1778, his strictures on an account of the same voyage, which had been published by John George Forster, who, with his father, had been on the same voyage, were both published at London, by Foulis, J. G.) In this work the accuracies made by the elder Forster against the captain and his officers are shown to be entirely without foundation.

In 1776 Mr. Wales again embarked with Captain Cook in a disapproved, as it is the case, the island, or Cape, is now supposed to have been that which was, in 1808, discovered by the Swan and the Otter in 54° 29' S. lat. and about 2° E. long. from Greenwich.

Mr. Wales is said to have been the author of the dissertation on the hemispherical rising of the Pleiades, which is annexed to Dr. Vincent's Voyage of Nearchus.

Walhalla, one of the most remarkable architectural monuments of the present age, stands on the brow of a hill on the north bank of the Danube, and about 250 feet above the river, the foundations being laid by Maximilian I. It was completed in 1821, the ceremony of laying the first stone did not take place till Oct. 18th, 1830, and exactly twelve years afterwards, October 18th, 1842, the building was solemnly inaugurated.

Though the title of the edifice is sufficiently appropriate and expressive, being that of the paradise of the Scandinavian mythology, consequently suitable enough for what is a Teutonic Pantheon, commemorating Teutonic intellect and genius, it seems quite at variance with the ancient character, which is strange to feel the title to be so extremely important as it is in itself, this circumstance has given rise to much captious objection, it being contended that a structure so eminently national in its purpose and in name ought to have been no less strictly national in style, and that if...
should have presented nothing to call up any ideas of Greece, or any classical associations. Even had the present discrepancy been avoided by selecting a name less in direct opposition to its architectural physiognomy, the propriety of adopting such style at all, or any other than the Grecian or Roman, would have been very questionable; still there are considerations, which, if they do not surmount all objections, may reconcile us tolerably well to what has been done. Unless it had been upon a much more extensive scale, an edifice in the Gothic style would have looked diminutive, especially in comparison with some of those colossal fabrics of the kind which are the architectural boast of Germany. There is reason too for apprehending that it would have partaken too much of a religious character—have looked very much more like a church than a national pantheon and shrine of monumental sculpture. The experiment would have been rather a hazardous one at the best, since, with all their study of their national antiquities, the Germans have not yet been very successful in imitating the architectural style of their ancestors; whereas, by copying the Doric, though oriental, it has been disowned, all the danger attending experiment has been avoided, and what is in itself a most noble monument of art has been ensured.

It might be supposed that the Walhalla was not a mere copy of the Athenian edifice, for it exhibits the Parthenon reared aloft upon a widely-spreading enormous substructure of Cyclopian masonry, forming successive terraces and flights of steps leading up to the platform on which stands the Doric temple itself, decorated with a portico and porch, which might be said to be without precedent, as no instance of any similar arrangement in antient temples has been preserved to us, for of that at Pireneæ [Temple, p. 183, col. 2] no more remains than to show that such was originally its disposition. In case therefore, the Parthenon itself becomes only a portion of the general design—the superstructure crowning a colossal architectural mass, to which it is in a manner what the dome of St. Paul's is to that edifice. Consequently, though the temple portion itself may look almost as a smaller than would denote it as the substructure, the whole becomes infinitely more imposing, more picturesque, and more varied in aspect, as viewed from different points, and more or less foreshortened as seen from below. In geometrical elevation the whole is of nearly pyramidal outline, and the temple seems to stand immediately over the ascent up to it, but in the real building the appearance is very different, owing to the manner in which the terraces and first flight of steps are brought out in advance of it.

The terrace is only a third of a mile in length, and from a considerable distance that the general outline and mass display themselves, for on approaching and beginning to ascend the visitor loses for a while sight of the temple itself, until he reaches the last flight of steps leading immediately up to it, when it is seen all at once into view, with its magnificent pediment. This is well contrived, the effect being far more impressive, and conveying an idea of greater magnitude than were the building seen during the whole course of the approach to it. Owing also to the ascent returning parallel to each other and to the building, views are obtained in different directions and at different heights; while the terraces and their colossal masonry, which show scarcely at all in a more general prospect or drawing, when seen close at hand and immediately before it, from the substructure, are overpowering, and the enormous substructure or basement rises altogether 138 feet to the level of the upper platform. Instead of being enclosed on its sides by pedestal walls, carried up horizontally, the first or lowermost flight of steps has merely low perpendicular walls, and is intersected by two or three passages, none more than 13 feet wide. Between the enormous substructure or basement rise altogether 138 feet to the level of the upper platform. Instead of being enclosed on its sides by pedestal walls, carried up horizontally, the first or lowermost flight of steps has merely low perpendicular walls, and is intersected by two or three passages, none more than 13 feet wide. Between the steps ascending. On the lower terrace there is a bronze door (marked on the plan), which forms the entrance of a spacious crypt or vaulted hall beneath the Walhalla, called the Hall of Expectation, and intended both to give more immediate access to the interior, and to serve as a repository for busts of eminent persons who are still living, and are afterwards to be removed into the Walhalla itself.

The Walhalla forms externally a magnificent Doric octastyle peripteral temple, with its principal front facing the south. It is entirely constructed of white marble, and is of nearly the same dimensions as the Parthenon, being 104 by 225 feet; the columns and entablature 45 feet high, and the pediment 12: making, with the substructure, a total height of 195 feet. In beauty of material and execution it may fairly be allowed to rival its original, and it gives a complete idea of what the Parthenon itself must have appeared in its perfect state; for it exhibits not merely the semblance of Grecian architecture, but its characteristic grandeur of construction, the blocks of marble being of the Waldenses dimensions, and those forming the architraves about 18 feet in length. All the details, including antefixe and acroteria, are most carefully studied, and beautifully finished; and yet there is one species of decoration peculiar to the order which has been omitted, there being no sculpture in the metopes of the frieze. The reason for this omission however is sufficiently apparent, because, owing to the situation of the building, sculpture would have been entirely lost, except as giving a general expression of richness; for seen from below it would not have been distinguishable, and viewed near would have been seen so very near and so immediately from beneath, and would have been so greatly foreshortened, as to be unintelligible. Still there is a most magnificent display of sculpture, and in a truly classical taste in the two pediments, after designs by Rauch, which were modelled and executed by Schwanthaler. That of the south pediment consists of fifteen figures in full relief, the one in the centre (of colossal size and seated) representing Germany, and the others symbolical of the different Germanic states. The sculpture of the other pediment, which is entirely the work of Schneller, consists of the same number of figures, representing the victory obtained by the Cheruscii over the Romans.

Of Grecian temples the beauty was confined almost entirely to the exterior, there being no architectural display of any kind within, or very little; but the interior of the Wallhalla is of most striking splendour—most sumptuous in point of decoration, and highly original in its design, which exhibits great happiness of invention. Here Klenze shows himself not an imitator of the ancients, but their rival—their pupil, but also a master in his art. The arrangement will be sufficiently understood from the plan, which shows that it consists chiefly of a single hall (150 by 57 feet), with a space answering to the opisthodomus...
of an antient temple, at its north end, but separated from it only by a screen of Ionic columns, which order is continued throughout in the ante at the angles of the magnificent pilasters, which divide the hall into these compartments. The entire length of the interior therefore becomes 175 feet, and though there was nothing to prevent the whole being laid into one uninterrupted space, the division serves to give the idea of greater extent, and greatly tinges the pantomime may be said with regard to the piers, whose boldly projecting masses break up what would else have been the too great monotony of the plan, and produce a pleasing succession of parts. Besides being of essential service in supporting the roof, the Ionic columns, in some measure screens, and prevent the disagreeable formality that would attend the ranges of so many busts all of the same size, on each side, if they were all exposed to view at the same time. What more than anything else gives the plan of this room an original character, and unborrows architectural character, is the construction and decoration of its roof, and the mode in which the light is admitted through it. According to the original design, it was intended that there should be a vaulted and coffered ceiling; yet, as that would have been too much at variance with the strictly Grecian character of the exterior, the architect afterwards conceived the idea of omitting ceiling or inner roof altogether, and adopting a single or open roof, without masking of any kind. There is therefore no contrast between the external and internal mass in this latter; the former becomes highly expressive of the first, and is made to repeat one of its most beautiful characteristics, namely, the pediment, which feature is obtained within the building by the sides of the roof, and the horizontal cornice being carried across from the opposite piers. Besides their expressive form and the effect attending a series of them, these internal pediments are rendered exceedingly decorative, their faces being divided into panels filled in with rich open-work arabesques and figures, in white and gold, partly relieved with colours. The ceiling itself is a dazzling splendour, being almost entirely lined with plates of gilt bronzes, and with gold stars, and other ornaments on an azure ground in its coffers. Through this the light is admitted in light or circular expanse, a part of the deposit of the plan, which follows the form of the roof, and is filled with sheets of plate-glass framed in bronze. Thus the whole is most effectively and beautifully lighted within, without either windows in the walls or lanternia on the roof.

With what has thus far been described all the other decorations of the interior are in a corresponding style of magnificence, and all of the most costly workmanship and material—white and coloured marbles, bronze, gilding, polychromy, sculpture. The coloured marbles from Tegerusse, distributed into three larger compartments answering to those of the plan. The shafts of the ante and columns are of a brownish red marble, resembling the antique African, and their bases and capitals are of the same. There is a kind of column with coloured glass, and yet it seems to be grained; while the walls are lined with the same material, and of nearly the same hue as the columns. In the entablature the architrave and cornice are white, relieved by gold and greens on their mouldings; but the frieze, which is of unusual depth, is entirely of white marble, and with only one exception, is without interruption by the piers, and where that part is decorated with small panels of sculpture, a continuous bas-relief, representing the progress of civilization in Germanic races from the earliest times to the introduction of Christianity by St. Boniface. This stems over the whole length of the sculptured panel, extends altogether to two hundred and thirty feet, was composed by Wagner and executed by Petrich and Schlopf.

Besides this principal Ionic order, which is 204 feet high, there is a second one (174 high) of colossal Caryatides, representing Valkyria, the female genius in Scandinavian mythology, whose office it was to welcome the souls of the blessed into the halls of Odin and the Walhalla. Of those figures there are two over each pier, which is not carried up solid higher than the first order, so that they stand detached from the walls, and thereby give an air of lightness to the upper part of the interior. These statues, of which there are altogether fourteen, six on each side and two over the嘲笑 at the farther end, where there is an upper gallery above the opisthodomus, were executed by Schwantaler, and are of marble, but slightly polychromed, after the chryso-elephantine fashion of the antients, in imitation of the great colours, "silver and gold, crimson and sapphire." The order, which was also in some degree termed Inosc, inasmuch as the figures bear voluted capitals on their heads, is raised upon a podium of greyish marble, and the frieze of its entablature is ornamented with precisely the same devices that are cut in the sculptured slab over the ante, and thereby have been read by the antiquaries who have described it. It is Imperfect in as it is, this description of the architectural decorations has detained us so long, that we may seem to have overlooked the principal objects of all—the very works for which the structure was erected as a repository. Namely, the effigies of the illustrious persons here commemorated. In regard to mere busts being adopted instead of statues, as would seem more befitting so sumptuous a pantheon, it may be observed that, besides the impossibility of having anything like the same number of heroic busts as there are figures in the original design, we so far appeared to have got rid of, namely, that which would have attended the strange variety of costumes: for while that of the older periods would have been more or less imaginary, that of more recent times would frequently have been formed a most grotesque contrast with the edifice itself; whereas the busts all partake of the same classical character, and are in perfect keeping with the architecture. They are also skillfully arranged, so as to show that they are parts of a whole, rendered by the introduction of columns, which, though they appear too much crowded, being confined to two rows, the lower one of which is placed upon a continued pedestal of beautiful yellow marble, the others on consoles; and, as presiding over the respective groups of busts, there is each one a statue, more grand in form and genius; also antique marble seats and marble candle-labrb. In short the whole arrangement is eminently tasteful; full of contrast and variety, without the slightest confusion. Equal study has been bestowed on every part of the building, and every ornament, from being a mere restoration or copy of the Parthenon, or designed merely according to antient precedent, that the interior is a perfectly fresh architectural conception, faithful to the spirit of Grecian art, and giving no countenance to such absurdities as the little room above the ante. No other edifice of modern times is so intensively Grecian, or so highly elaborated as a monument of art. A truly monumental fabric it certainly is, being so constructed that it may be preserved for many ages, as such there will hand down the memory of its royal function and architect to a distant posterity, which, along with the names of Pericles and Phidias, will place those of Ludwig of Bavaria and Leo von Klenze.

WALKER, J. J., D. L. A. H., was born at Worsnough, near Barnesley, in the West Riding of Yorkshire, probably in the year 1616, and was educated at University College, Oxford, where he took his degree of M.A. in July, 1638, and was chosen Fellow of his college in August following. In 1640, while he was thirty, he showed himself to be a man of high talent, being admitted to seats in the University in holy orders. Becoming now very distinguished as a college tutor, he remained at Oxford till he was expelled from his fellowship by the parliamentary visitors in May, 1646; on which he retired to Rome. On the Restoration he was re-nominated in his fellowship; but he soon after made another visit to Rome in the capacity of travelling tutor. Returning home in 1649, he might then have been elected master of his college, but declined the appointment. He accepted it however on the death of Dr. Richard Cromwell in 1658.

Walker's tutors at Oxford had been Mr. Anderson and Mr. Abraham Woodhead, both of whom appear to have been then inclined towards popery; which Woodhead after wards openly professed. Their instruction seems to have led him to Rome; where he probably remained till the same faithful line his election to the mastership of University College. Indeed it is asserted by Anthony Wood that at the time of his appointment to this office he was actually residing in Oxford, and in his seminar at Magdalen or Hoxton, near London, in which young men were educated in the Roman religion. It was not however till 1670 that

* In the number of the Civil Engineer and Architect's Journal for April, 1840, will be found an excellent account of this sepulchral repository, and how it was opened to the public by the late Mr. Lord, and other works in the Walhalla, arranged chronologically, beginning with Herodes Atticus, 1849, and terminating with Goethe, 1842.
attention was drawn to his principles and conduct by the publication of his Latin translation of Sir John Spelman's Life of King Alfred, which appeared at Oxford in a magnificient folio in 1678. In October of this year, in the ferment excitated by the death of Sir Edmundby Godfrey, complaint was made in the House of Commons of the dangerous tendency of some of the notes to this work, and also of Walker's connection with the seminary at Hoxton. But no consequences followed; and, although the matter was mentioned again in April, 1679, the master of University College came and still held his ground; but only, had he ceased to celebrate in his lodgings, but converted two of the rooms of his college, forming the lower half of the side of the quadrangle next the chapel, into a Romish chapel, which he opened for public use on Sunday, 21st of August, 1686. He at the same time obtained a mandate from the king to sequestrate the revenue of a fellowship towards the maintenance of his priest, and erected a statue of James over the entrance of the college gate; and the next year he set up a press in the back part of his lodgings, in the hope of making his escape with the payment of certain of his claims to his majesty, for the avowed purpose of printing books against the established religion. Many tracts, principally written by Woodward, issued in the course of the next two years from this press.

The former things of course made him a marked man when the Revolution came. He left Oxford on the 9th of November, 1688; and on the 11th of December following, he, Andrew Pulton, a Jesuit, and others, put themselves into a coach at London, in the hope of making their escape; and set out. But during his stay in London, was seized all papists that attempted to leave the kingdom, the party turned back. They were however pursued, seized, and carried first to Faversham, and thence to London, where Walker was committed to the Tower. On the 13th of December, according to the account of the doctors of the University declared him no longer master of University College; and on the 15th of the same month his place was filled up by the election of Edward Ferrer, the present master.

On the 23d of October Walker was brought up by habeeus corpus to Westminster Hall, and sued for bail; but he was immediately sent for, with other prisoners in the same circumstances, to the bar of the House of Commons, where he was examined, and was denied that he had ever altered his religion, the principles which he now professed being, he said, the same which had been taught him in his youth by his tutor Mr. Anderson, that he was remanded to the Tower on a charge of sedition, to be placed and launced in the Tower. Being again brought up to the court of King's Bench, he was allowed to give bail and was set at liberty; nor was he further troubled, although he was excepted out of the Act of Pardon soon after passed (the 2 Will. & Mar., sess. 1, c. 10). He spent the remainder of his days in retirement, and partly abroad; but he died at London, on the 21st of January, 1699, in the house of Dr. Radcliffe, who was one of his old pupils, and by whom he had been for some time principally supported. He was buried, at Radcliffe, in the churchyard of the parish church, and so, the common place of interment of London Roman Catholics of the upper classes.

Walker, who is admitted in all hands to have been a man of learning and talent, is the author of, or connected with, of which the principal are: a Brief Account of Antient Church Government, 4to, Lon., 1662; a 12mo. tract, titled "Of Education, especially of Young Gentlemen," first printed at Oxford in 1673, and for the fourth time in 1693; a Latin treatise on the "Prerogative of Princes;"" The Marshalls of the Realm, and Membrum Nominalium, Libri Tres," 8vo, Oxford, 1673; "Some Instructions concerning the Art of Oratory," 2nd edition, 4to, Oxford, 1682; "An Historical Narrative of the Life and Death of Our Saviour Jesus Christ, &c.," 8vo, Oxford, 1685 (the sale of which was procured by the vice-chancellor of the University, on the ground of the alleged papish tendency of some things in it); "Some Instructions in the Art of Grammar," 8vo, Lon., 1691; and "The Greek and Roman History illustrated by Coins and Medals," 8vo, Lon., 1692; a work which formerly had a high reputation.

WALKER, CLEMENT, is known as the author of a work entitled 'The History of Independence,' the first part of which was published, in a small 4to, under the pseudonym of Theophilus Versi, in 1648, in two editions, one much more extended than the other; the second (a much more considerable volume) in 1649; the third, under the title of 'The High Court of Justice, or Cromwell's New Slaughter House,' in 1651. A fourth edition, by Dr. John Drury, who calls the book, "The Life, Letters, and Times of his King, and Country," appeared in 1661, along with a reprint of the other three parts, in which the second has the new title of 'Anarchis Angliae.' In this edition the work is entitled "The Compleat History of Independence," and is very scarce, but the first part has been reprinted by Baron Maspero, in his 'Select Tracts relating to the Civil Wars,' 2 vols. 8vo, 1815.

The little that is known of the personal history of Clement Walker is chiefly to be found in Wood's "Athenea Oxonienses" and in his own work. He was born at Cliffe, in Dorsetshire, towards the close of the sixteenth century, and there he appears to have spent the early part of his life: the register of that parish, according to Hutchins, in his "History of Dorset," gives the date of his birth as 1629, the baptisms of three sons of Mr. Clement Walker and Frances his wife: Thomas in 1626, Anthony in 1629, Peter in 1631. Wood mentions another son, John, "sometimes a commoner of Lincoln College, Oxford." This John was, it would seem, that Mr. Ferrar, who, having studied at Christ Church, entered the University, but no record of his matriculation there remained. Before the breaking out of the contest between the king and the parliament, he lived, Wood tells us, on an estate he had at Charterhouse, near Wells, in Somerset, and the whole of the country was under the control of the Exchequer. At this time he was reputed both a sound royalist and a good churchman, holding puritanism as well as dissent in avowed dislike. Nevertheless, when matters came to a crisis he declared himself for the people, and was made as one of the members for the city of Wells to the memorable second parliament of 1640. But notwithstanding what is thus asserted by the Oxford antiquary, we must not too hastily assume that Walker at this time really changed either his professions or his principles. He appears to have continued to the end of his life attached to the monarchical part of the constitution, and he had probably been from the first opposed to the excesses of prorogative. In parliament he necessarily acted with the whole party of parliament, and in that sense his course they followed, to his own principles, and his ability and reputation for integrity soon acquired him considerable ascendancy with his party. But his book is by no means, as it has been generally represented, an indistinguishable part of the proceedings of Cromwell and his associates. Yet his work has preserved a good many minute facts not elsewhere to be found; and although the author sees no sense, and no good of any kind, either to the right hand or the left of the middle way in which he and his friends attempted to walk, it throws a considerable, though it may be a highly-coloured, light on the events and characters of the time. Walker also published anonymously several other short tracts against the republican government, a list of which, although as they are known, is by no means complete; the most important of them are incorporated in his History. His authorship of that work was discovered soon after the appearance of the second part, upon which he was immediately consigned by Cromwell to the Tower, where he was for some time kept in confinement. When the news of his arrest was sent to the press, the third part of his History, which, as may be conjectured from the title, is the most violent portion of it, was not recover until in October, 1651.

Walker was one of the two principal witnesses (William Prynn being the other) of Colonel Fiennes, before the council of war, at St. Albans, in November, 1643. He was the recorder of Bristol. (See the proceedings in State Trials, iv. 483.)
316. Lord Clarendon upon this occasion describes Walker as 'the painter of all of Somersetshire, of a good form, and by the loss of that the most spoilt; who had been in the town when it was lost, and had strictly observed all that was done.'

WALKER, SIR EDWARD, is said to have been the son of a Catholic gentleman, Sir Walter and Mrs. Roobers, in Netherstowe, Somersetshire. In early life he appears to have held some office in the household of Thomas, twelfth earl of Arundel (the collector of the Arundelian Marbles), and, having accompanied that nobleman as his secretary on the expedition to Scotland in 1639, he then became known to Charles I., who, taking him into his service, made him his secretary-at-war, and to that end, in June, 1644, the appointment of clerk extraordinary of the privy council. In this latter year also, while he was with the king at Oxford, the treaty was referred on him the degree of M.A.; and, in 1645, he received the honour of knighthood. After the execution of his royal master, Walker fled to Charles II., whom he accompanied to Scotland in 1650, and, after the failure of that enterprise, remained in the Continent. Charles, during his exile, made him Garter King at Arms; and, after the Restoration, he was appointed one of the clerks of the privy council. Both these offices he held till his death, at Whitehall, 19th February, 1677.

Walker's mention of Charles II. is said to have been commissioned by Lord Clarendon, whom he is said to have assisted in the parts of his history which relate to military transactions.

In 1659 there was published in London a folio volume, entitled 'The History of Four Monarchies, upon several occasions, by Sir Edward Walker, Knight, &c.' It is dedicated to the queen in an address signed Hugh Clopton, and there is also a dedication of the Discourses by Walker himself, 'to his grandchild, Edward Clopton, Esq. of Clopton,' dated 1659, followed by a postscript dated 1674, in Stratford-on-Avon, directing them to make public after his death. It is quite clear that all the Discourses were printed for the first time in 1659. In 1820 was published, in London, in an 8vo volume of 131 pages, with plates, a new and accurate account of all the preparations, ceremony, &c., on the coronation of his Majesty King Charles the Second, and a minute detail of that splendid ceremony, &c., from an original manuscript by Sir Edward Walker, Knight, Garter principal King at Arms at that period.

The common biographical accounts attribute to Sir Edward Walker a work on tactics, entitled 'Military Discoveries,' published in folio, in 1675; and also the following works, which are stated to have appeared in his lifetime, but the dates of none of which are given:—'Iter Carolinum,' however, appears to have been contained in the 'Historical Discourses,' the first of which is entitled 'The History, Progress, and Success of the Arms of King Charles I., from 30 March to 23 November, 1644,' written by his Majesty's special command, and corrected almost in every page with the 'second,' 'of his Majesty's unfortunate success in the year following.' The fourth discourse is entitled 'Observations on L'Estrange's Annals of Charles I.;' and the eighth is a Review of the entire reign of that king. The third is a 'Journal of the ExpDITION to Scotland,' and the fourth is 'A Discourse of the Last Happy Peace.'

A complete list of Walker's works is not easy to make, and a summary of his life and career is not easy to give. He was a soldier, a sailor, a politician, a writer, a painter, and a wit. He was a man of many parts, and a man of many talents. He was a man of many friends, and a man of many enemies. He was a man of many passions, and a man of many vices. He was a man of many virtues, and a man of many virtues. He was a man of many weaknesses, and a man of many weaknesses. He was a man of many merits, and a man of many merits. He was a man of many faults, and a man of many faults. He was a man of many mistakes, and a man of many mistakes. He was a man of many successes, and a man of many successes. He was a man of many failures, and a man of many failures.

WALKER, ROBERT, a clever English porttrait-painter contemporary with Vandyck, and the principal painter employed by Cromwell. Walker painted several portraits of Cromwell, but his most celebrated work was his portrait of the Protector, which was hung in the Pitt Palace at Florence. It was purchased by the reigning grand-duke in Cromwell's lifetime for 500l. He sent a pension to his family for the entire duration of his life. Walker had a very high reputation as a portrait painter of the Protector. The agent had much difficulty in procuring one to his satisfaction; but he at last found this by Walker, in the possession of a lady who was related to Cromwell, and who, being unwilling to part with the portrait, refused to sell it. During the interview, the agent asked him what appeared to her the exorbitant sum of 500l. for it. The amount was however immediately paid, and she was obliged to part with her picture. Another was in the possession of Lord Mountford, at Horsham is the painter's design for the engraved portrait of the Protector, all the features of which are carefully observed and transmitted to the engraver by Mr. Creswell, who found it at an inn in the county. There is a gold chain upon Cromwell's neck, to which is appended a gold medal with three crowns, the arms of Sweden, and a pearl: it was sent to him by Christina of Sweden to celebrate his return from the campaign. The emblem is engraved on the Latin epigram. There was another in the possession of the earl of Essex at Cusahury; and a fourth in Lord Bradford's collection, with the portrait of Lambert in the same piece. It was one of these portraits that Lebrum wrote the following eulogy on:

'By lines oth' face and language of the eye,
We find him thoughtful, resolute, and stily.

'From one of R. Symonds's pocket-books,' says Walpole, 'in which he has set down many directions in painting, and with whose suggestions he has been confronted, return.' Walker's portrait of the Protector is said to have been painted both in the life and death, and to have been painted both in the life and death. Walker's portrait of the Protector is said to have been painted both in the life and death. Walker's portrait of the Protector is said to have been painted both in the life and death.
serving the strictest discipline under the most difficult circumstances, and dividing himself between the most opposite duties,—now heading a scholarly party, now reviving the war under the guise of a rousing sermon in the cathedral. The end was the same: the sedition was suppressed, raised, on the 30th of July, by Major-General Kirk making his way with three ships over a boom which James had thrown across the river. Walker soon after came over to England, and having published a pamphlet in which he had been engaged, under the title of 'A True Account of the Siege of Londonderry,' in a quarto pamphlet, he received in November the thanks of the House of Commons for his heroic exertions. His account provoked some of his assailants in a vindication published the same year; this was followed by an anonymous 'Apology for the Failures charged on the Rev. G. Walker's printed Account,' also 4to, 1689; and that by a 'Narrative of the Siege,' &c., and by various pamphlets abusing him, as having been one of his assistants in a vindication published the same year, which was answered the same year by a friend of Walker's, in another quarto pamphlet, entitled 'Mr. John Mackenzie's Narrative of a False Libel.' Meanwhile Walker, having been created Doctor of Laws, and having been nominated Bishop of King William to the bishopric of Derry; but having resolved to serve another campaign before entering upon his episcopal duties, he was killed at the battle of the Boyne, 1st July, 1690.

The British Museum a pamphlet of ten pages, entitled 'The Substance of a Discourse, being an Encouragement for Protestants, or a happy prospect of glorious success, &c., occasionally (sic) on the Protestants' victory over the French and Irish Papists before Londonderry, in raising the siege, 1689,' he is called 'A Discourse on the Governor of the City, London, printed by A. M. in the year 1689.' This was probably a reporter's publication. Prefixed on the title-page is a rude wood-cut, which seems to have been a print for a portrait of Walker.

WALKER, JOHN, D.D., was born Cambridge, in the parish of Friern-Barnet, Middlesex, 18th March, 1732, and was brought up to trade, but adopted the profession of an actor, which he followed with no great success till 1766, when he quit the stage, and joined Mr. James Usher in establishing a school at Kensington Gravel-pits. This partnership lasted only about two years, after which Walker set up for himself as a teacher of elocution, and soon became greatly distinguished in that capacity. Not contenting himself with England, he went to Ireland, and to various provincial towns, especially Oxford, where early in his career the heads of houses invited him to give a course of private lectures in the University. He soon also began to employ the aid of the press in disseminating his instructions, starting a journal which he professed. The settlement of the pronunciation of the English language upon analogical principles, and according to the best usage, was certainly attempted by Walker more systematically than by any preceding writer. There is a great deal of sound sense in his work, which are by good sense and careful inquiry, as well as a respectable amount of information, cannot be denied to have done considerable service in that matter. His first publication was a prospectus of his Pronouncing Dictionary, under the title of 'A General Idea of a Pronouncing Dictionary of the English Language,' which he printed in quarto in 1772. This was followed in 1775 by 'A Dictionary of the English Language, answering at once the purposes of rhyming, spelling, and pronouncing,' afterwards reprinted, at least twice, under the title of 'A Dictionary of the English Language,' in which the whole Language is arranged according to its Terminations, &c. In 1781 appeared his 'Elements of Elocution,' which has gone through many editions. In 1783 he published a pamphlet, entitled 'Hints for Improvement in the Art of Eloquence,' and a small tract he afterwards incoporated in his 'Rhetorical Grammar,' first published in 1785, and since often reprinted, as well as his 'Academic Speaker,' and two or three other similar compilations. In 1797 he published a small tract, entitled 'The Melody of Speaking delineated, or Elocution taught, like Music, by visible Signs,' which is not much known. His 'Critical Pronouncing Dictionary, and Expositor of the English Language,' the work which had occupied most of his life, and upon which his reputation principally rests, first appeared in 1791. It has been eminently successful, having since gone through between twenty and thirty editions, and having superseded all other previous works of the same nature. In the preface of the latter edition he again his 'Key to the Classical Pronunciation of Greek and Latin Proper Names,' which was first published a few years after the Dictionary, and of which there are also many editions in a separate form. His last publication was his 'Outlines of English Grammar,' which appeared in 1805. Mr. Walker, who was brought up a Presbyterian, but became a Roman Catholic, and a very strict one, in his latter days, died 1st August, 1807, and was buried among his co-religionists in Old St. Pancras church-yard, London.

WALKER, REVEREND, is the author of a work entitled 'An Attempt towards recovering an Account of the Numbers and Sufferings of the Clergy of the Church of England, Heads of Colleges, Fellows, Scholars, &c., who were sequestered, harassed, &c. in the times of the late great Rebellion,' published in 1779. The Ninth Chapter (now the Second Volume) of Dr. Calamy's Abridgement of the Life of Mr. Baxter, together with an Examination of that Chapter, folio, London, 1714. It contains a long list of subscribers, is dedicated to 'The Archbishops, Bishops, and Clergy, now assembled, without Convocation,' and commences with a preface of above 90 pages, in which the author gives a very detailed account of his sources of information and the extensive researches he had made both in printed books and in public and private papers of the worth-while kind of two parts, the first in 204 pp., the second in 436.

On his title-page the author designates himself 'M.A., Rector of St. Mary's the More in Exeter, and sometime Fellow of Exeter College, in Oxford.' In Watt's 'Biography of the Bishops, Bishops, and Clergy, now assembled, without Convocation,' and there are attributes to him, besides the above-mentioned work, two single Sermons, both published in 1710, and 'Conscience Dissembled, in several Discourses on Acts xxiv. 16,' 8vo, 1723. But whether different writers be meant, or one and the same, there is a mistake in Salt's 'Biographical Dictionary.' Walker is stated to have been a native of Devonshire, to have been, after the publication of his work on the Sufferings of the Clergy, complimented by the university of Oxford with the honorary degree of D.D., and to have died at Exeter in 1720. This information professes to be given on the authority of the 'Biographia Britannica,' but there is no account of Walker, either in that work or in any of the other collections of English biography which we have had an opportunity of consulting.

Walker's 'Account of the Sufferings of the Clergy' has been severely attacked for its misstatements and exaggerations by Puritans and dissenting writers. It was republished after its first appearance by permission of the publisher, entitled 'The Church and Dissenters compared as to Persecution;' and also by the Rev. John Withers, a dissenting minister of Exeter. Several of its assertions are disputed by Neal, in various passages of his 'History of the Puritans;' and there is a great deal of股份 in the book as preserved in the third volume of that work, published in 1733, in which it is denounced as written 'with notorious partiality, and in language not fit for the lips of a clergyman, a scholar, or a Christian.' It must be admitted that Walker was a man of a coarse and violent temper, who could not be held responsible for any critical judgment, and with little learning or ability of any kind: he boasts indeed of his unusual ignorance of the history of the time to which his work relates when he undertook its compilation, as rather a qualification for the task which he undertook. It is true, and with a great deal of justice, it is said that he, partly from incompetency, partly from haste, he has set down many things upon the most insuffcient authority. His style is illeterate to the point of barbarism, and he contains particularly of the labours the position he held for writing for the other part of the work, after all deductions that may justly be made from the value of his book, it must be allowed to have preserved much curious information that in all probability would otherwise have been lost. It is true, that the number of the episcopal clergy who were imprisoned, banished, and sent a starving, to have amounted to seven or eight thousand.

WALKER, a genus of plants named after Richard Walker, D.D., who was founder of the botanical garden at Cambridge. It belongs to the natural order Oenocarpus.
and is known by possessing five petals, five stamens with ovate anthers; an obovately kidney-shaped fruit, which is a drupe; an inverted embryo with a hooked beak. There are two species of this genus known. *W. serrata* has serrate crenate leaves, racemes of flowers somewhat syrnbome, and the lobes in garden lanceolate. It is a native of Malabar and Ceylon, and has yellowish flowers and reddish fruit. The roots and leaves are very bitter, and are used in decoction by the inhabitants of Malabar as a tonic and anthelmintic. *W. integrifolia* is a native of French Guiana, and has entire leaves.

WALL. [Staffordshire.]

WALL, PICTS, ROMAN, &c. [Britannia; Northumberland.]

WALL-CRESS, the common name of the plants belonging to *Arabis*, an extensive genus in the natural order Cruciferae. Nearly seventy species of this genus have been described; they are mostly of small plants, fond of growing in dry stony places and on walls, and hence their English name—*Wall*. Their fruit is a linear siliqua, with flat 1-nerved seeds. The seeds are oval or orbicular, compressed in one row in each cell. The cotyledons are flat. The radical leaves are usually stalked, whilst those of the stem are sessile, or embrace the stem; they are entire or only rarely lobed. The petals are confluently covered with hairs, of which those on the stem are simple, whilst those on the leaves are bifid or trifid. The flowers are white in most instances, rarely red. Several of the species are natives of Great Britain, and many of them are indigenous to gardens. One species from rock-work and foot-paths, on account of their blooming early in spring.

*A. turrita*, Tower Wall-Cress, has leaves embracing the stem; the pods all on one side, recurved, flat, and lined with woolly hairs. This plant is a native of Europe, in Spain, France, Switzerland, and Italy. In Great Britain it appears to be almost an entirely academic plant, as the only localities mentioned are the walls of colleges at Oxford and Cambridge.

*Wallsia*, by Wall-Cress, has hairy toothed leaves, numerous straight pods, and the pedicels the length of the calyx. It is a native of middle and northern Europe, and also of North America, from Hudson's Bay to the Rocky Mountains. In Great Britain it is found in Sussex, Norfolk, and Suffolk, and also in Hampshire.

*A. rosea*, Rose-flowered Wall-Cress, has oblong, subcordate, half-stem-clasping leaves, covered with branched hairs; the pedicels longer than the calyx, and the stigma appressed. It is a native of California, and has rose-purple flowers.

*A. albidula*, White-leaved Wall-Cress, has toothed leaves, hoary or downy, with branched hairs. It is a native of Taurida and the Caucasus. It has large white flowers, and is a tufted plant, often cultivated in English gardens.

Several other species of the genus resemble these examples. They are of easy cultivation, and when once sown they will mostly propagate themselves.

WALL-FLOWER. [Cheiranthus.]

WALL-FLOWERS, the common name of the species of *Cheiranthus* of the natural order Cruciferae. This genus is known by possessing square or compressed siliques; a 2-lobed or capitulate stigma; a calyx bisaccate at the base; ovate compressed seeds in one series. The species are biennial or perennial herbs, or under-shrubs. The leaves are oblanceolate, lanceolate, entire, or toothed. The flowers are arranged in racemes, and are of various colours—yellow, white, purple, or parti-coloured. Many of the species exude a delicious colour, and are cultivated for their fine foliage in gardens. The most plentiful is the *Cheiranthus Cheiri*, the common Wall-flower, which has lanceolate entire leaves, which are either smooth or covered with 2-parted appressed hairs; linear pods and recurved lobes of the stigma. It is found wild throughout Europe, and in low places, and in among fens and meadows, amongst the ruins of old castles. On this account it is a great favourite with poets, and is popularly regarded as an emblem of faithfulness in adversity. The general colour is a brown-yellow, or, as a poet has called it, the 'yellow wall-flower stained with brown.' It is however subject to considerable varieties of colour even in its wild state, and these are much increased by cultivation. On account of its scent, it has been transferred from raised walls to the flower-borders of gardens, and there, by the doubling of its flowers and the variations of its colours, a number of distinct varieties have been recorded. The following is a list of the most remarkable varieties found in gardens:

- **a. flore simplici.** Single yellow.
- **b. flore pleno.** Double yellow.
- **γ. maximus.** Large-flowered yellow.
- **δ. gigas.** Large, saw-ledged. Double yellow, spreading.
- **ε. petulans.** Double rosy.
- **ζ. ferrugineus.** Double, variegated with purple and yellow.
- **η. flavescens.** Large, double, pale yellow.
- **θ. thyroides.** Bunch-flowered, yellow.
- **ι. gynanthus.** Flowers with anthers changed into carpels.
- **ν. hemiandrus.** Single and double, bloody-flowered.

The Wall-flower is a common wild plant in Great Britain. It possesses the slight acridity of the order to which it belongs. The flowers are in racemes, and may be propagated by cuttings, which soon strike root when planted in a bed of sand and peat. Of the various species in this genus none are more suited to the purposes of the gardener than the Wall-flower, *Cheiranthus*.

A number of other plants deserve the name of wall-flowers, as they are found growing on old walls; the most common of these are the Reseda luteola, some of the species of Antirrhinum, the Asplenium ruta maris, and the various *Donum*'s Wall-Cress, the Arabis, and the *Pranthere.*

WALL-PELLITORY. [Wall-Pellitory, the Arabis, Wall-Cress, the Pranthere, &c.]

WALL-PELLITORY, the common name of the *Parietaria officinalis*, a plant belonging to the natural order Urticaeae. The genus *Parietaria* has several species. One of them, given the name *Parietaria officinalis*, is distinguished by having a quadrifid inferior perianth; stamens with incurved filaments, and a one-seeded fruit inclosed in the enlarged perianth.

The *P. officinalis*, Wall-Pellitory, or Pellitory of the Wall, grows in lanceolate 3-lobed leaves, and the flowers in two portions, each of about 7 segments; in each portion are 3 flowers, with one fertile one between them. This plant is the same as the *P. erecta* and *dissecta* of German botanists. It is common throughout Europe in rocky places, and is found only in England, where it is a weed of gardens and waste places amongst rubbish. The stems of the plant are often procumbent upon the wall on which it grows, and are of a reddish colour. The flowers are small, hairy, a purplish green colour, and clustered in the axils of the leaves. The leaves are finely fringed along the borders, which under some circumstances have a stinging power, similar to many plants of the order to which they belong. The filaments of the stamens are jointed, and possess a remarkable physiologic property; the flower first opens, the filaments are found bent over the stigma; but when the time has arrived for the anther to shed its pollen, the filament flies back from the stigma with considerable force, and entirely empties the pollen-case of its pollen by jerking. The same plant has been found when the sun first shines on the opened flower; but it may be easily effected artificially by touching the anther with the point of a pin or other instrument. This phenomenon was first observed by Caspar Bauhin, in 1600, and a full account of the situation of the flowers of this plant is given in Curtis's *Flora Londinensis*. The wall-pellitory was at one time admitted into the Materia Medica of the London and Edinburgh Pharmacopoeias, but it is now abolished. It was recommended as a diuretic in diseases of the kidneys, and also as a purifier of the blood in cutaneous diseases.

Farmers are in the habit of placing a bunch of this plant on corn affected with weevils, which, it is said, quickly drives away.

WALLACE, Sir William. The life and exploits of this most popular national hero of the Scots have been...
principally preserved in a legendary form by poetry and tradition, and are only to a very small extent matter of contemporary record or illustrated by authentic documents. There is no extant Scottish chronicle of the age of Wallace. Fordun, the earliest commentator, is silent, and the most trustworthy of the chroniclers, man in whose account of the life of the one bat upon and to one of his early contemporaries, is by the next author, still half a century later. His chief character is the metrical writer Blind Harry, or Harry the Minstrel [Vol. xii., p. 56], whose work contains an account of the commencement of Wallace's career as a hero, and whose extant at any rate is supposed to be nearly two centuries subsequent to that of his chief. Some few facts however may be got out of the English annalists Trivet and Hemingford, who were the contemporaries of Wallace.

There are contradictory statements of the year of his birth, but it is probable that he was born about 1270. His family was one of some distinction, and he is said to have been the younger of the two sons of Sir Malcolm Wallace. Fordun, who held the office of steward of Ayrshire, in the neighbourhood of Paisley. His mother, who, according to one account was Sir Malcolm's second wife, is stated by the genealogists to have been Margaret, daughter of Sir Raynald or Reginald (other authorities say Sir Hugh) Crawford, who held the office of sheriff of Ayrshire. The history of Wallace down to the year 1297 is entirely legendary, and only to be found in the rhymes of Harry the Minstrel; though many of the facts which Harry relates also still live as popular traditions in the country, where Wallace was born and brought up. It has been handed down in that way from the time when they happened, or only derived from his poem, which long continued to be the chief literary favourite of the Scottish peasantry. Harry, who, it may be observed, professes to translate from a Latin account written by Wallace's intimate friend and chaplain, John Blair, makes him to have been carefully educated by his uncle, a wealthy churchman, who resided at Dunipace, in Stirlingshire, and to have been afterwards sent to the grammar-school of Dundee, where he was taught the liberal arts. He is said to have been performed, his slaughter of the son of Selby, the English governor of the castle of Dundee, in chastisement of an insult offered him by the unwary young man: Wallace struck him dead with his dagger on the spot. His father, it is said, after Edward I. of England had obtained possession of all the places of strength throughout Scotland on his recognition as Lord Paramount by the various competitors for the crown, which had become vacant by the death of the infant Margaret, the Maid of Norway, in September, 1290.

This bold deed committed by Wallace, who in making his escape is asserted to have laid several of young Selby's attendants as low as their master, was immediately followed by a second exploit. Wallace, who is asserted in this life to have been eloquence, sagacity, and other high mental powers and accomplishments (to this the testimony of Fordun is as express and explicit as that of his poetical biographer), not less than with strength and height of frame was also noted for his courage. He discharged from the head of a band of attached as well as determined followers, who under his guidance often harassed their natural enemies the English soldiery, both on their marches and in their stations, plundering and ravaging, as might elsewhere be the case. Particular spots in nearly every part of Scotland are still famous for some deed of Wallace and his fellow-outlaws performed at this period of his life; but for these we must refer to the Blind Minstrel. The world is full of stories about the height of the wall which was said to have been his chief haunt; and some of his most remarkable feats of valour were exhibited in that town, in the face and defiance of the foreign garrison by which it was occupied. Both his father and his elder brother are said to have been murdered in the city by the English, and their chiefs. It was now also that he fell in love with the orphan daughter of Sir Haw de Bradfute, the heiress of Lumington, being, it is said, first seen her at a church in the neighbourhood of Lanark. The Scotch writers affirm that the lady, whom he appears to have married, and who was in reality but a daughter, a year or two after gaining her connection with Wallace fell into the hands of his enemies, and was barbarously executed by order of Hadingen, the English sheriff or governor of Lanark, while her husband, or lover, was deemed to witness the spectacle from a place where he lay in concealment. Such private injuries were well fitted to raise his public hatred to an unextinguishable flame.

How far the guerrilla warfare maintained by Wallace and his associates contributed to excite and spread the spirit of resistance to the English government, we have scarcely the means of judging; but it seems probable that it aided materially in producing the general insurrection which broke out in the spring of 1297. The accounts we have of the movement are derived in part from the traditions incorporated at its head, in command of a considerable force, and in association with some of the most distinguished persons in the kingdom, such as the Stewart of Scotland and his brother, Wishart, bishop of Glasgow, Sir William Douglas, &c. After he was made prisoner (afterwards King Robert I.), who had hitherto, as well as his father, still alive (the son of the original competitor for the crown), professed to adhere to the English king.

This however appears to have been but an ill-considered confederacy. When the force dispatched by Edward to quell the revolt presented itself before the Scottish army posted near Irvine, in Ayrshire, the leaders of the latter, throwing off the authority of their nominal chief, could no more agree what to do than whom to obey; and the stock of that Sir Henry, or Sir Andrew, Stewart, and his companions, was supposed to be quite gone, availing themselves of the diplomatic talents of the Bishop of Glasgow, concluded a treaty on the 9th of July, by which they agreed to acknowledge Edward as their sovereign lord. All the rest ultimately succumbed to this armistice, except Wallace, who was conveyed to London, and held by Monravay of Bothwell. The treaty of Irvine, which is printed by Rymer, and, we believe, the first of the few public documents in which mention is made of Wallace: to the English, was expressed in these words, 'Ecclesiæ Sire Wallææ; ' the meaning of which Lord Hailes conceives to be, 'that the barons had notified to Wallace that they had made terms of accommodation for themselves and their party.' The words moreover, on the condition that they refer to Wallace, of which there can be little doubt, show that he had before this date obtained the honour of knighthood. It had probably been bestowed upon him (as was then customary) by some other knight, one of his companions in arms, since his elevation from being the captain of a body of ruffians to be the commander-in-chief of the national forces.

Wallace now retired to the north, carrying with him however a considerable body of adherents, to whom additional numbers rapidly gathered, so that he soon found himself in a condition to resist the movements of the English. Directing his force on the north-eastern coast, he surprised the castle of Dunottar, cleared Aberdeen, Forfar, Breechan, and other towns of their English garrisons, and then laid siege to the castle of Dundee. He had already, it seems, brought that the English army was approaching Stirling; upon which, leaving the siege to be carried on by the citizens of Dundee, he hastened to meet the enemy in the field. The result was the complete defeat and rout of the English at the battle of Stirling Bridge, fought on the 11th of September, 1297—a battle which once more, for the moment, liberated Scotland. The English were immediately driven or fled from every place of strength in the country, including Berwick itself.

Availing himself of this panic, and of the exhalation of his countrymen, Wallace even pursued the fugitives across the border; and putting himself at the head of a numerous force, he entered England on the 18th of October, and reduced the country with fire and sword from sea to sea, and as far south as to the walls of Newcastle. It was during this visitation that the prior and convent of Hexham obtained from him the protection of Henry II. it was at Hexham [Haxham 7th of November, and runs in the names of Andreas de Moravia, et Willelmu Wallacici, deces exercitus Scottiae, nomine praecellentis Principis Dei gratia, Regis Scottiae illustrissimi, tali regni ajudicio, in quibus Anderson Moray and Wallace, commandam-in-chief of the army of the name of King John, and by consent of the name of the said kingdom. The home he was the King of Scotland was Balliol now in the stately plaine and living in a sea at a behest in the hands of Wallace's associate in the command of the army.
Andrew Moray, son of his faithful friend of that name who had retired with him from the capitulation of Irvine, and who had fallen at the battle of Stirling Bridge.

One of the most curious of the few public papers in which the name of Wallace is mentioned, has only been recently discovered, by Dr. Lapenburg of Hamburg, in the archives of the ancient Hanseatic city of Lübeck. It is a letter, in Latin, addressed to the authorities of Lübeck and Hamburg, informing them that their merchants should now have all the ports of the kingdom of Scotland, seeing that the said kingdom, by the favour of God, had been recovered by war from the power of the English. The letter is dated 'Apud Badingstonam [the true word, it has been suggested, is probably Haddingston], the 11th day of August, 1297,' that is, the assumption of Cumberland and Northumberland. It is in the name of 'Andreas de Moravia et Willelmus Wallensis, duces exercitus regni Scottiae, et communis scidem regni—liber parens Principatus et Dominus de Moravia et Willelmus Wallensis, et communis scidem regni—libertatem et amicitiam, &c.'

The discovery was first announced, not quite accurately, in the 'Foreign Quarterly Review' for August, 1829; and the letter was, we believe, first printed in the Appendix to 'The Life of Sir William Wallace, by John F. Cooper,' London, 1829, pp. 544, 545, in that year.

After his triumphant return from his invasion into England, Wallace assumed the title of Guardian of the Kingdom in the name of King John, whether formally invested with that dignity, or only hailed as such by the gratitude of his fellow-countrymen, as a charter, a diploma, conferring the constabulary of Dundece on Alexander Skirmishur [Scrimgeour] and his heirs, and dated at Torphichen (in the county of Linlithgow) the 28th of March, 1298, he styles himself, "Willelmus Walays miles, Ordinarius, vescendi et durandi usque ad domi praeclaris principis Domini Johannis, de grauit Regis Scottiae illustres, de consensu communis ejusdem Judicis.'

The grant is stated to have been made with the consent and approbation of the nobility ('per consensum et assentium magni dicti regni').

But this supreme elevation did not last long. Supported only by his own merits and the admiration and adhesion of his fellow-countrymen, Wallace, a new man, and without a family connection, would probably have found it difficult or impossible to retain his high place, even if he had had nothing more to contend with than domestic jealousy and dissatisfaction. Fordun relates that many of the nobility were in the habit of saying: 'We will not have this man to rule over us.' Meanwhile, the English king, who had been abroad when the defeat at Stirling Bridge lost him Scotland, had now returned, and was already on his march towards the borders, at the head of a large army. A body of English, who had landed in the north of Fife, led by one de Valois, Earl of Pembrokeshire, is said by the Scottish authorities to have been attacked and routed by Wallace on the 12th of June, 1298, in the forest of Blackcounside, in that county; but obliged once more to submit to an attack at Sighthill, in the neighbourhood of Falkirk—the Scots commanded by Wallace, the English by their king in person—the former, after a gallant and obstinate resistance, were at last forced to give way, and the battle ended in a universal rout accompanied with immense slaughter.

This defeat did not put an end to the war; but it was taken advantage of by the Scottish nobility to deprive Wallace of his merits of guardian or chief governor of the kingdom. The Scottish accounts say that he voluntarily resigned the supreme power; but it appears certain, at any rate, that Bruce, his rival Comyn, and Lambert, bishop of St. Andrews, were now appointed joint guardians of Scotland, still in the name of Baliol. For some years after this our melancholy hero was slighted or obscure; but he was not content to have remained a private citizen in Fenchurch Street: on the next day, being the eve of St. Bartholomew, he was brought on horseback to Westminster, and in the hall there, 'being placed on the south bench,' says Slow, 'he was crowned with laurel, for the English king did say to him, "You right to bear a crown in that hall,"' he was arrayed as a traitor, and on that charge found guilty, and condemned to death. After being dragged to the usual place of execution—the Elms in West Smithfield—at the stroke of noon, he was there hanged, drawn and quartered, on the 23rd of August, 1303. After which, his bowels having been taken out while he yet breathed, and burnt before his face, his head was struck off, and his body hacked into quarters. His right arm was set up at Newcastle, his left at York, his right thigh at Derby, his crown and his head on London Bridge. Wallace's daughter by the heiress of Lamington married Sir William Baillie of Hoprig, whose descendants through her inherited the estate of Lamington.

The CARPATHIAN, or WALACHIA, or WALACHIA (Zira Rumunia, in Wallachian), is a principality and a vassal state of Turkey, or more correctly of Turkey and Russia. Its limits are, on the north the Carpathians and the principalities of Moldavia; on the east that part of the Rumanian province of Transylvania, which is between the Danube, and on the west the Danube and the south-eastern corner of Hungary. Its greatest length from west to east is 276 miles, and its greatest breadth from south to north is 200 miles; the extreme miles of 60 to a degree of latitude, or 26,649 English square miles; the population is 970,000, according to the same authority.

The Carpathians are the principal mountains. Several ranges of lower mountains and hills stretch from the Carpathians in a parallel direction south and south-east, and contain valleys between them, the upper part of which is narrow, but the lower part becomes wider as the valleys approach the Danube. Above the confluen of the rivers near the Danube of lowlands and marshes, which are exposed to the inundations of the river. However the most western part of Wallachia is generally mountainous, and the hills reach to the banks of the Danube. A great part of the northern part of Wallachia is covered with forests of firs, oaks, and beeches. The soil, except in the mountainous districts, is a rich mould, and of extraordinary fertility. In the elevated part of the country the thick forest is mostly extinguished, and great numbers of deer and wild hogs frequent the mountains, which feed a great number of sheep, the flesh of which is as much esteemed as that of the sheep of Transylvania. In the level and marshy parts there is excellent pasture for cattle, of which great numbers are annually fattened. The principal river is the Danube. [Danube.] The other rivers are tributaries of the Danube; their sources are all in the Carpathians, and their direction is south in the western.
part of the country, south-east in the middle part, and east in the eastern part. The principal are—1, the Syl or Sis, which comes from the Tatra Mts., enters at Arjish, and

enters this country by a long and narrow defile called the 

Valkan Pass, where it enters Wallachia; it joins the 

Danube opposite the small town of Rahoza in Bulgaria; 

its length is nearly 140 miles. 2. The Alt or Aluta, east 

of the Arjish, above the town of Arjish, is the common 

source of several rivers and is about 140 miles long. The 

sources are in 45° N. lat., between the Alt and the river 

Arjish, at the foot of the Carpathians; it joins the 

Danube opposite the town of Novgorod in Bulgaria, after a 

course of 108 miles. 3. The Zarkam, a tributary of the Alt, 
a river of 162 miles, joins the Danube between the town of 

Pass, and the Arjish, after an eastern course of 120 miles. All 

these rivers are in the Carpathians, 20 miles east of the 

Drothehurn Pass, and it joins the Danube opposite the 

Bulgarian town of Turtuki, after a south-eastern course of 

100 miles. The Dumbrowitza is a tributary of the Arjish, 

which it joins 16 miles north of the junction of the Arjish 

with the Danube; its course is in the south-west parallel to the 

Arjish, and its length is 110 miles. 5. The Janoltz or 

Yandelon comes from the Carpathians near the Tomosh Pass; 
at first it runs south for 30 miles, and afterwards south-east, 

crosses, and north-east till it reaches the Danube a little below 

Hirzewa; its whole course is nearly 170 miles. 6. The 

Buza, north of the Janoltz, comes from Transylvania, 

flows through the pass of Boszu or Buza, and joins the 

Sereth 12 miles above the junction of this river with the 

Danube, after anastern course of 120 miles. All these 

rivers are in the Carpathians, 20 miles east of the 

Danube, and in the rainy season, or when the snow on the 

Carpathians melts, the low tracts along the Danube are 
inundated for many miles in breadth.

Climate and Productions.—The summers are exceeding 

hot, but the climate is healthy, except in the marshes, where bilious fevers 

prevail during the warmer months. The temperature is much 

colder in Transylvania and Moldavia. The waters 

are abundantly supplied with fish; the trout in the 

streams and the Danube are highly esteemed, and 

the navigation, which is rendered impracticable in 

many places by rocks, shallows, and other obstacles. 

Besides the larger rivers, there are many smaller streams 

which traverse the country. In the marshy districts there 

are lakes, some of which are considerable. 

The vine grows well, and the produce is 

amount, and would be equal to the best Hungarian wines 

if the inhabitants had more skill. The 'Rhamnus' 

viticus' yields annually 600,000 oaks (a little more than a pound 

and a half, the sixth part of the oka of Coafantimile) 

of red, which goes chiefly to Transylvania, where it is used 

for dyeing cloth, and especially twist. In the time of 

Wilkinson, about twenty years ago, there were about 2,500,000 

sheep in Wallachia, and gave a supply of wool, which, 

of which about 1,760,000 oaks were annually 

exported. There are three different kinds of sheep, 

producing three different sorts of wool: Zigay, which is 

short and very fine; Zarharm, which is long and coarse; 

and Tartar, which is intermediate. The Zarharm 

covers a little so short and fine as the Zigay. There 

is abundance of game of every description: 300,000 hare- 

skins are yearly exported. There is plenty of timber, but 

it is not in the forests. Only the third part of the country is 

cultivated, a consequence of the system of extortion and 

oppression which formerly prevailed in Wallachia. One 

third of all the lands belong to the clergy. The commerce 

was in former times entirely in the hands of the Jews and 

Armenians, and was of little importance, but it has con-

siderably increased during the last thirteen years. The line 

of steamers established between Vienna and Constantinople 

has put Wallachia in direct communication with both 

these capitals. Several English, German, and French 

merchants reside at Bucharest, and the Bar 

Government.—The government is in every respect like 

that of Moldavia, from which country the political history 

of Wallachia is inseparable. [Moldavia.]

Towns.—Bucharest, or more correctly Bucharesti (Buc- 

aresti)—Tergoviast, for more correctly Tergoviast, north-west of Bucharest, was the capital of 

Wallachia till 1698, when the seat of government 

was transferred to Bucharest. Tergovist is situated on the Jalo-

nitsa, and contains about 5000 inhabitants; the whole 

town is covered with ruins of houses and palaces, which 

were abandoned by the nobility after 1698. The road from 

Bucharest to Kronstadt in Transylvania, leads through 

Tergovist. Ghinargewo, on the Danube, opposite Rushtuk, 

was formerly a strong fortress, but the fortifications were 

altered in consequence of the mentioned Turkish 

seat of a bishop, is a small town. Ardisch or Arjish, on the 

Arjish river, towards its source, lies on the road from 

Bucharest to the pass of Rothenhurn and Hermannstadt. 

There is a beautiful church in this thriving little town, 

which is said to be the seat of Wallachia. It is a small 

but busy town, a little west of the junction of the 

Aluta with the Danube. Krajova or Krayova, a fine town 

with about 8000 inhabitants, has considerable commerce; 

it is situated on the Sty, in the centre of Little Wallachia, 

and is the western point of the line of communication 

with the north, east, and Hungary and the Danube on the west. 

Krajova is generally called the capital of Little Wallachia. 

Brajow, on the Danube, ten miles south of the junction of 

the Arjish with the Danube, in the north-eastern corner 

of Wallachia, was the capital of Peter, one of the 

Danube; but its fortifications have been (or are to be) 

razed, pursuant to the terms of the peace of 1829. It is 

also called Braila. The town sustained many sieges against 

the Russians, who have taken it several times. Rimmik, 

which must not be confounded with Rimmik, in Moldavia, 

lies west of Brailow. In its vicinity is Okna-Mare, where 

there are rich mines of rock-salt. The great road from 

Yassy to Bucharest leads through Rimmik. Fokshan, or Fokszan, 

is partly in Moldavia. [Moldavia, p. 304.] The southern 

larger part is called Little Wallachia. Inhabitants.—The majority of the inhabitants are Wallachians, besides whom there are 50,000 (?) gypsies, 20,000 Jews, 5000 (?) Armenians, and 3000 Greeks.

Origin and History of Wallachia.—The Wallachians 

are not confined to Wallachia; they inhabit Moldavia 

and parts of south-western Russia; they are very 

numerous in Transylvania and eastern Hungary; they form 

part of the population of the Bukowina, and they are 

very numerous in Transylvania. They are fair, and 

Euprates. Their number has been estimated at three 

millions; but this estimate is rather low, and apparently does 

not comprehend the Wallachians of Macedonia and the adjacent 

countries, or the Kutscho-Wallachians, who form a very considerable part of 

the population of that part of the country. As the 

Wallachian language is apparently derived from that of 

the Thracians, it is generally supposed that the Wallachians are the 

descendants of the Roman colonists sent by Trajan into Dacia. But this is 

a mere hypothesis, and some well ascertained facts show that this opinion cannot be maintained.

It is true that after Trajan's time the Latin language 

made considerable progress in Dacia, but it is also true that 

the emperor Aurelian, when he ceded Dacia to the 

Goths, recalled the Roman provinciates (provinciales) from 

Dacia and gave them back to the Roman nation, the people of 

Vopiscus (Aurelianus, c. 39). There is not the slightest 

trace of a Roman population having lived in Dacia during 

the next eight centuries after Aurelian, and the name 

Wallachians is unknown in the history of Dacia during that 

time. But the Thracians, Macedonia, and Thessaly, though not before 

the ninth century, as we know from the Byzantine historians, who 

frequently mention the Vlachi (Bàgya), who lived chiefly 

in the country round Mount Pindus. In the twelfth 

century a remarkable species of the Vlachi, who were 

called by the name of Vlachs, by the Emperor Manuel, concluded an alliance with the Bulgarians and the 

Cumanians, who inhabited Bulgaria and Dacia, and, commanded 

by two brothers, Asan and Peter, left Thrace and settled 

north of the Danube. In the beginning of the thirteenth 

century the inhabitants of Dacia were exterminated by the 

Mongols; and after the Mongols had withdrawn, num-

born of foreign colonists, Bohemians, Moravians, Germans, and especially Wallachians, flocking, some to Transylvania, and others to the present countries of Moldavia and Wallachia, which thus received a new population. Sulzer states that the MS chronicles of the Wallachians contain very good accounts of these migrations, which we also find mentioned in the Annales of Hungary and Transylvania, and it is always said that these Wallachians received certain lands to settle upon. It is in a document concerning a donation which King Bela IV. of Hungary made to the Knights of St. John, in the year 1231, that the names of the Wallachians first appear in the history of Hungary. These Wallachians were boiers, and lived in Transylvania. Three causes seem to have contributed to induce the Vlachi to settle north of the Danube—the origin of the Greeks, emperors and nobles, the invasion of the Turks, and the opportunity of acquiring fertile lands and liberty in a country beyond the reach of the emperors and the Turks. Thus the inhabitants of Wallachia, Moldavia, and a great part of Transylvania and Hungary might be considered as descendants of the ancient Thracian nation, belonging to the Greek church, and who used a kind of Roman language, as we still see from the Kutzio-Wallachians. That this Roman language was used in a considerable part of the Thracian peninsula is stated by the Greek historian, Duque de Benavente, who says that after the conquest of Macedonia by the Bulgarians, that is, in the twelfth century, these barbarians proceeded to the conquest of the Provinsia Latinorum which then temperate Romans vocabantur, modo vero Moraviach, hoc est Niger Latinorum vocantur. It is also considered that the Wallachians are Greek Christians, but that no facts are known in ecclesiastical history from which we can conclude that the Greek religion was introduced into Wallachia by missionaries, as was the case in Russia. This circumstance however does not exist, when the Wallachians and their present country, they were already Greek Christians, and did not require missionaries. In short, the hypothesis that the Wallachians are the descendants of the Roman colonists in Dacia appears to be as untenable as the opinion according to which the Greeks in Transylvania are the descendants of the Goths. However the fact that the Wallachians are descended partly from the Romans is proved by their language and their name.

Most Wallachians call themselves Rumanian or Roman. As the name Wallachians, which is given them by foreigners, several hypotheses have been proposed. The name is said to be derived from Wloch, a Servian word signifying 'a shepherd,' or from the Voloch, a Turkish name of the Danubian basin in Russia. It is however that the word Wallach comes from the Slavonic Wzech (with a barred i), which among the Poles, the Servians, and other Slavonic nations still signifies an Italian, or a Roman, and seems to be the same as the German Wallach, which signifies a foreigner. It follows, that for the Romans, either a French or an Italian, though its original meaning was rather a 'foreigner.' It cannot surprise us that the name of Blachi or Vlachi was given to these Romans before they emigrated to the north. From the seventeenth century, even earlier, a great part of Thrace, Macedonia, Thessaly, Epirus, and Greece was occupied by Slavonic nations which mixed with the primitive Greek inhabitants, or in other parts with the Romanized nations. Hence the origin of the Wallachian language.

The language. According to Thurneysen, who has written half of all the Wallachian words are Latin, and of the remaining half three-eighths are Greek, two-eighths Gothic, Slavonic, or Turkish, and three-eighths belong to a language which seems to be mixed. The suffixes, the pronouns, the greater part of the prepositions, and the adverbs of place and time, as well as the numerals, the declensions, and the conjugations, are all Latin, and so is generally the groundwork of the language. The declension of the Nominative is (1) Sing. Nom. kîny; Dat. kînî; Acc. pe or pre kînî; Voc. kînî; Ablat. de la kînî: Plur. Nom. kînî; Gen. a kînîlor; Dat. kîinîlor; Acc. pe or pre kînî; Voc. kînî; Ablat. de la kînî (2) Sing. Nom. dûmûna (the mistress); Gen. a dûmûnîlor; Dat. dûmûnîlor; Acc. pe or pre dûmûnî; Voc. dûmûnî; Ablat. de la dûmûnî: Plur. Nom. dûmûnîlor; Gen. a dûmûnîlor; Dat. dûmûnîlor; Acc. pe or pre dûmûnî; Voc. dûmûnî; Ablat. de la dûmûnî. The auxiliary verb fi or fire (to be) goes thus:—Pres. Ind. Yeu sun; Inle, yestî, noo sunîn, wee sundî, yeu sundî; Conj. fi, fi.
mathematician and a famous astrologer. He continued his studies at Pavia and Bologna, where Argoli, the astronomer, taught him the principles of the Cabala. Besides the Cabala and astrology, Albrecht acquired a thorough knowledge of the antient and almost all European languages; of the Roman, the canon, and the German law; and of mathematics and other sciences connected with the military art, which was always the chief object of his study. He was more than twenty years a student at the university of Altdorf, where he signalized himself by many extravagances, if we may trust the stories with which credulous contemporaries or later generations have disfigured the memory of the most lofty genius of his time. Albrecht had hoped to see his name become illustrious, but Waldstein believed it. He always believed in astrology, and in later years the astrologer Seni was one of his principal counsellors.

Anxious to signalize himself by military deeds, Waldstein, in 1605 went to Hungary, where the imperial armies were fighting against the Turks. At the siege of Gran he was amongst the foremost stormers, and his commander-in-chief, General Basta, appointed him captain on the walls of the conquered fortress. After the peace of Sitterau, in 1606, he married an old but wealthy widow, Lucretia Nikessin, baroness of Landeck, who died in 1614, and left him fourteen large estates in Moravia. During his marriage, and till 1617, Waldstein devoted himself exclusively to the management of his family concerns, a double farmer; he increased his wealth by economy; and he disposed of large sums in the banking-houses of the Fugger and Welser, at Augsburg, who were then the richest mercantile houses in Europe. He was also a patron of the emperor's goons, with which he assisted the archduke Ferdinand of Austria, duke of Styria, who was at war with the Venetians; he saved the festival of Gradicia, which was hard pressed by the Venetians; and by paying his soldiers well, and keeping open tables, he became the idol of the Styrian army. In a short time he saw himself at the head of several thousand men, and, after the campaign was finished, towards the end of 1617, to the advantage of the archduke Ferdinand, the emperor Matthias made him his chamberlain and colonel in chief. Immediately afterwards he married Isabella Catharia, the daughter of count Harrach, who was the favourite of the emperor, who, on this occasion, conferred upon Waldstein the dignity of a count of the Holy Roman Empire. The state he in 1618 appointed him colonel of the Bohemian and Moravian militia; and at the outbreak of the war between the Bohemians and the emperor, the Bohemians offered him an independent command in their armies. The Protestant members of the family of Waldstein were partly assisted and partly injured by the emperor, who showed much less from religious than from political motives, refused to make common cause with the Bohemians, in consequence of which the Moravian states deprived him of his command of the militia, and confiscated his estates. Waldstein sided the emperor, and having been created a count of Bohemia, was created count of Italy. He immediately took the field, and with Frederic von Cal- latine, who had been chosen king by the Bohemians. The counts Mansfeld and Thurn having advanced as far as the neighbourhood of Vienna, and attacked the imperial general Boucquet, near Tulln (1618), he hastened in the assistance of Boucquet, defeated the enemy, and thus saved the emperor from being made a captive in his own capital. In the battle on the Weisses Berg, near Prague (5th of November, 1620), the cavalry of Waldstein, on being charged, held their ground. Through these charges, but Waldstein was not present at the battle, being obliged by his commission as quartermaster-general to procure the necessary supplies for the imperial army. It seems that, the resources of the emperor being exhausted, Waldstein gave large sums for the support of his master, for which however he got an ample indemnification. After the overthrow of king Frederic of Bohemia, the estates of his adherents were confiscated, and the greater part were either sold by the emperor Ferdinand II. or given as rewards to his faithful servants; on many occasions also Ferdinand used to combine generosity and in- terest by selling them at a low price. The reward of Waldstein was the lordship of Friedland, worth about 600,000 guilden, for which he paid 150,000 guilden; and he bought more than sixt, other lordships and estates, the value of which was estimated, at a very low rate, at 7,290,228 guilden, of which however Waldstein only paid a part, his sacrifices and services being taken into account. As the value of money was then at least three times less than to-day, the amount of the property acquired by Waldstein in consequence of his services, was at least 24,000,000 guilden (3,000,000,000) according to the present value of money; to which must be added the value of his personal estate.

Waldstein retired by his triumph nor by his wealth. In 1621 he took the field against Betten Gabor, the prince of Transylvania, who stood on the frontiers of Germany, and was going to effect a junction with John George, marquess of Brandenburg-Jagarndorf, who had encamped near the town of Bulgnitz, within the frontiers of the then province of Silesia. Waldstein successively defeated both his adversaries, prevented their junction, and forced Betten Gabor to sue for peace, which was granted on condition that he should give up his claim to the crown of Bohemia, which he had acquired by the death of Sigismund of Brandenburg. Waldstein was principally occupied with the management of his estates. But Betten Gabor having again taken up arms against the emperor, Waldstein hastened to Hungary, and arrived just in time to save the imperial army under the direction of the emperor Charles, of which he was one of the generals. He distinguished himself in the battle of Giiding, on the frontiers of Moravia, by the prince of Transylvania, count Thurn, and John George of Brandenburg-Jagarndorf. As a reward for this victory, the emperor, in 1624, created him the baron of Giiding, and the prince of Transylvania, count Thurn, and John George of Brandenburg-Jagarndorf. put in motion by the power of his genius, this heavy body advanced with irresistible rapidity. On the 21st of August Waldstein was at Cottbus; on the 27th at Havelberg; and on the 30th he took Dömitz in Mecklenburg, after having performed a march of 250 miles in eight days, through a marshy ground on which it would be difficult to perform for a modern army unaccompanied by heavy ordnance and moving on excellent roads. On the 27th of September, his lieutenant, count Schlick, defeated the Danes near Aalborg in Jütland, and king Christian saved the remnants by flying with his troops and coming into the Danish islands. Waldstein hastened to the Belt, and it is said that, being unable to cross this channel for want of ships, in a fit of anger he ordered the sea to be bombarded with red-hot bullets. This war was finished by the peace of Lübeck (12th of May, 1629). Waldstein’s reward were the duchies of Mecklenburg, with which he was invested by the emperor on the 16th of June, 1629, after the dukes Adolphus Frederick and John Albert had been dissolved in them, for felony, in an imperial decree in 1628. Waldstein choose Wismar, the best port for a navy on the southern coast of the Baltic, for his residence, and obtained from the emperor the title of Admiral of the Baltic and the Queen’s Lieutenant in the German shipping. The Swedes have charged him with childish vanity. His plan was to form a navy with the assistance of the Hanseatic towns, and to prevent Gustavus Adolphus, the king of Sweden, from choosing Germany for the theatre of his ambition. The emperor of Germany was determined that the Swedes should have penetrated the secret views of that king. ‘Bitt,’ wrote he to his lieutenant Armín, ‘der Herr hab fleissig Aufsicht auf den Schonen, denn er ist ein gefährlicher Gist’ (‘I beg you, sir, to observe well the Swede, for he is a dangerous fellow, for he is a very unscrupulous merchant, and to have him under his dominion and subject to him’). ‘I should like to have the Swede for my friend, but that he should not be too strong, for love and power cannot agree.’ At a moment when his funds were almost exhausted, the ordinance of the king had fixed the annual cost of dollars to be raised immediately, which he intended to give as a reward to a certain merchant who was to do something in Sweden. It has been pretended that Waldstein had formed the plan of murdering Gustavus Adolphus, but in the summer of that year it is certain, and it is said that the merchant had proposed to turn the Swedish fleet in Karlskrona. The plan was not put into execution. During the siege of Stralsund, Waldstein cried out that he would have the town if it were fastened to the sky with iron chains. Such was his power and influence on the king, that he could have made himself a powerful member of the Ligue, by the extraordinary success of the imperial arms, the power and influence of the Ligue, of which Maximilian was the head, had become secondary. Tilly hated Waldstein as his greatest rival. The pride of the princes of the empire was hurt by the elevation which, though a Bohemian, was given to Waldstein as a reward of meritorious service. The emperor was only too pleased to make the Swede king’s lieutenant, and to give him the title of Admiral of the Baltic. Waldstein was a great Indian. His character was that of a bigoted Jesuit, avaricious, and ambitious of injurious use to his religion, a traitor to his country, and a traitor to his king. He was ambitious of the office of generalissimo, and he would not have been satisfied with the command he held. The emperor was the more ready to believe the accusation, as it transpired that France had offered to assist Waldstein to aid him in obtaining the crown of Bohemia; but Waldstein rejected these propositions, and continued to carry on his war against Germany, enemies as well as friends. The emperor ordered him to withdraw from Bohemia and Moravia, and to take up his winter-quarters in Lower Saxony (December, 1632). At this Waldstein neither would nor could obey this order, which he regarded as a violation of the conditions on which he
had resumed the command. Upon this Maximilian of Bavaria urged the emperor to dismiss his disobedient general. Waldstein, having been informed that the emperor had resolved to do it decided on the very morning of the 23rd of January, 1636, to resign his command. His faithful lieutenants urged him not to abandon them, for they were all creditors of the emperor, who paid them very irregularly, and they were sure they could make more money on the estates of Waldstein than they could on the estates of their commander should resign. In order to prove their invariable attachment, they signed a declaration at Pilsen, on the 12th of January, 1634, in which they promised to stay with Waldstein as long as he would be their commander. This is the oath of faith, and the Catholics, and The Hapsburgs at this time, and among the Protestant princes the wealth of the Waldstein estates had been appropriated to the fiscus. It has lately been reported that the present emperor, Ferdinand I., without waiting for the legal decision, has ordered those estates to be resold to Whigs, who would value them highly.

WALLER, SIR WILLIAM, a distinguished military commander on the side of the parliament in the civil wars of the seventeenth century, was of the same family of the Wallers of Spensiburth, in Kent, from which the poet Waller was descended, and was born in 1626. After finishing his studies for a time at Magdalen-hall and Hall-hall, Oxford, he went to complete his education at Paris; and while abroad he entered the service of the confederated powers (Sweden, Holland, and the Protestant princes of Germany) in the war which had carried on against the emperor after their league of the year 1628. On his return home he received from Charles I. the honour of knighthood. In 1640 Sir William Waller was returned to the Long Parliament for Andover; and he immediately took his seat among the members of the committee on the abstention of the clergy from ordination and service which had given him a strong attachment to Presbyterianism; and he had also, it is said, a热度, among the seventy members of the Star-chamber. On recourse being had to the committee for the appointment of members to the parliament, he was chosen as one of the most faithful officers, and among Tercey, Kinsky, Illo, Neumann, and some traitors, such as Gordon, Butler, and Leslie, who were bribed by Piccolomini, and had promised to execute the bloody order of the emperor.

On the 23rd of February, Charles, who was commander of Eger, gave a splendid entertainment to Waldstein’s officers, at which the duke was not present on account of his ill health. After dinner an armed band rushed in, and the friends of Waldstein fell beneath their swords. Waldstein himself was in his room, and观 window and asked a sentinel what it meant. Suddenly Captain Deveroux, at the head of thirty Irishmen, rushed into his apartment; and while his men shrank back at the sight of their great commander, he stood bold, his thoughts instantly turned to his escape. He was speedily captured, and was brought before the executioner. Deveroux, thus accused, cried out, ‘Art thou the traitor who is going to ruin the emperor?’ With these words he lifted his pistol. Waldstein, without uttering a word, opened his arms and received the deadly blow in his breast. He was always thought of, and spoke little, and so he was in his last moment: he fell and died silently.

His wealth was partly divided among his enemies, each of whom received a large share, for the revenue of Waldstein’s estates was 250,000/. (21,25,000. according to the present value of money). Part of his estates were kept by the emperor, who paid for 3000 dead masses to be read for the soul of his great general.

The present time has generally been believed that Waller was so over-served by the state of his enemies, which was sold for 3000 dead masses to be read for his soul, that he never saw the cardinal’s head; but the truth is, that Waldstein has never been proved. About twenty years ago Dr. Friedrich Forster from Berlin discovered many autograph letters of Waldstein in the family archives of the count of Arundel, at Berlin, in consequence of which discovery he was admitted, by order of the emperor Francis I., to the secret part of the archives of the military council at Vienna, which had hitherto not been used by the biographers of Waldstein and the Hapsburgs. Forster was a considerable number of letters, which he published under the title ‘Waldstein’s Briefe.’ Berlin, 1826-1829, 3 vols. 8vo.

Having been invited by the counts of Waldstein, who are descended from the brothers and uncles of Albrecht, to continue his researches, he was enabled to prove the complete innocency of Waldstein, and that he never was a traitor or the instigator of the rebellion. He published his results under the title ‘Waldstein, Herzog zu Mecklenburg, Friedland, und Sagan, als Feldherr and Landesfürst,’ 8vo., Potsdam, 1854, 1 vol. 8vo. The count has fought a suit against the Austrian fiscus for the purpose of recovering the Waldstein estates which had been appropriated to the fiscus. It has lately been reported that the present emperor, Ferdinand I., without waiting for the legal decision, has ordered those estates to be resold to Whigs, who would value them highly.
racter and conduct, which was published from his manu-
script, in 1805, with an introduction by the editor, at Lon-
don, in 1793. Both these works give a favourable impres-
sion of his honesty and ingenuousness, as well as of his
shrewdness and general intellectual ability; and the second is
of considerable historical value.

WALLER, EDMUND, a celebrated English poet, was
born 3rd March, 1605, at Coshelhill, in the county of Her-
ford. His father, Robert Waller, Esq. of Amersham, or
Amersham, in Buckinghamshire, in which parish Coles-
en, a daughter of an old Essex family, and had in early life followed the profession of the law. Edmund was the eldest of several sons and daughters, but he was still in his boyhood when his father died, leaving him an estate of 3,000l. a year, and his mother, daughter of Griffith Hampden of Hampden in Buck-
inghamshire, and aunt of the patriot, who was consequently the poet's cousin. The relationship, if it is to be so called, of Edmund Waller to Cromwell, about which there has been considerable historical value, is this. Waller's eldest uncle, William Hampden, the father of the patriot, having married Cromwell's aunt, Elizabeth; so that Hampden the patriot was first cousin both to the poet and to the pro-
tector. (Noble's Memoirs of the Protectoral House of
Commons, 1707, where Waller's family is erroneously set down at 33,000x. per annum, and his father is in one place called Richard, instead of Robert.) John-
son, whose account is copied without either correction or acknowledgment by Chalmers, makes Waller's mother to have been a daughter of the patriot, whose father he incor-
rectly names John.

Waller was educated at Eton, whence he proceeded to
King's College, Cambridge. His earliest biographer, the writer of a memoir prefixed to the edition of his poems published in 1640, says that Waller was a seat tenant of
the House of Commons, at the age of sixteen, for the borough of
Amersham. If so, he would appear to have been returned to the third parliament of James I., which met in January, 1621, and to which that borough of Amersham clung, as it clung for representation, after every effort ceased to do so ever since the second year of Edward II. The
claim was eventually allowed; but it may be doubted if
Waller, although he may have been elected, was permitted
to take his seat, at least was not regarded as a member, although he may have sat silentio, as was then some-
times done. No members for Amersham, or for Wendover
and Great Marlow, which were similarly circumstanced, are given in the common lists of this parliament. Whether Waller was returned to the next, and to the final parliament, which met in February, 1623, is not known; but it is probable that he was. In the first parliament of
Charles I., which met in 1625, he was returned for Chip-
ning-Wycombe. It is not certain that he sat in the next, and to which his name is given in the next year's enumera-
tion, which represented Amersham in Charles's third parliament, which sat from March, 1627, to March, 1629, and also both in the short parliament of April, 1640, and in the Long Parlia-
mnt which assembled in November of the same year.

The earliest of Waller's poems is commonly stated to
have been produced towards the end of the year 1623,
when the event which it celebrates happened, the escape of
the prince (afterwards Charles I.) from being ship-
warded in the road at St. Albans, on his return from
Spain. Yet it certainly was not published till some years
later; and not only the title "On the Danger his Majesty
(being Prince) escaped," &c., but even the verses them-
selves seem rather to imply that they were not composed at that time. It is, however, possible that the style and versification of this poem have
quite as much neatness and finish as those of his latest
days; so that, as has been said by one of his editors, as quoted by Johnson, 'were we to judge only by the word-
ing, we should say he knew what was the fashion of verse at fourscore.' Dryden has stated (in the preface to his
Fables') that Waller himself attributed the polish and
smoothness of his versification to his diligent study of Fair-
fax's translation of Thos. Clarendon says expressly that
at the age when other men used to give over writing verses (for he was near thirty years when he first engaged
himself in that exercise, at least that he was known to do
so), he surprised the town with two or three pieces of that
kind; as if a tenth Muse had been newly born, to cherish
dropping poetry.' In truth, there are only two or three of
his poems that could have been written before his twenty-
fifth year.

Some years before this date he had married Ann,
dughter of Edward Banks, Esq., a very wealthy citizen
of London, having gained the heart and hand of the lady
by his talents and the interest of the family, and he was in
favour of a rival suitor. By this match he considerably augmented his fortune. His wife, after bringing him a son who died,
and a daughter, who when she grew up married Mr. Dogmer of Oxfordshire, died in childbirth, and let him, as John Waller says, 'on a widow's of about five and twenty
gray and wealthy, to please himself with another marriage.
The older accounts make him to have lost his wife in 1629
or 1630.

It could hardly then have been, as is commonly rep-
resented, almost immediately or very soon after this that
he began to pay his addresses to the Lady Dorothy Sidney,
the eldest daughter of the Earl of Leicester, whom he
made famous in many of his love verses under the name of
Sarah. Some, however, who are enthusiasts in this case,
ins isted of his marriage in 1639 married Henry, lord Spencer, who, in 1643, was
created earl of Sunderland, and was killed in September,
the same year, at the first battle of Newbury. [Vol. xii.
p. 286.] As Lord Spencer at the time of his marriage
was certainly not nineteen, it is not probable that the
bride could have been old enough to be sought in marriage
eight or nine years before. sacharissa, who, after the death
of her first husband, married Mr. Robert Smythe, sur-
vived till 1683. Another of Waller's temporary attach-
ments at this time was to Miss Mary Bresse, of Eton,
whom he has celebrated under the poetical name of
Amoret. At last, soon after the marriage of Sacharissa,
but in what year is not precisely known, he married a
Miss Mary Bresse, or Beaux, of whom nothing is recorded
elsewhere. He was probably in the neighborhood of his
sons and eight daughters, and that she was, according to Aubrey,
the antiquary, distinguished both by her beauty and her
good sense.

When government by parliament was resumed, after an
interruption of twelve years, in 1640, and Waller found
himself again in the House of Commons, he joined the
party in opposition to the court, where, although his for-
tune, wit, and poetical reputation had made him a dis-
tinguished figure, he is said to have been admired by
and even suspected as the near kinsman of Ham-
pden. But his temper and position alike withheld him from
going very far with the reformers or revolutionists; and
on the approach of the crisis he seceded from his party,
and certain events having transpired, he found himself
in the king's set up his standard at Nottingham, in August,
1642, Waller sent him a thousand broad pieces; and,
although he soon after returned to his place in parliament.
he is supposed to have done so by his majesty's permission
of their right, and then in a letter from the king, 'not
of
the royal side— with great sharpness and freedom,' says
Clarendon, 'which, now there was no danger of being
ousted, was not restrained; and therefore used, as an
argument against those who were gone upon pretense
that they were not sufficient to give their opinions freely
in the House; which could not be believed, when all men
knew what liberty Mr. Waller took, and spoke every day
with impunity against the sense and proceedings of the House.'

Waller was one of the commissioners sent by the parlia-
mont to the king at Oxford, after the battle of Edgehill,
in January, 1643; and it was soon after this, in the end of
May, that the design known as Waller's plot was discov-
ered. It is difficult to say what was really the object of
this plot of Waller, or of the plot of Clarendon, to dis-
another which was detected about the same time—a project of a loyal London merchant, Sir Nicholas Crispe, to raise an armed force, when a fit opportunity should occur, to act against the parliament, for which purpose he had obtained a commission of array from the king. Waller's embassy was attended by a professed confederate, Mr. Tomkyna, who held the office of clerk of the queen's council, and had an extensive connexion and influence in the city; and their proceedings were discovered, according to one account, by a servant of Tomkyna, who, while lurking behind the house during a conference between his master and Waller; according to another version of the story, by a sister of Waller, who was married to a Mr. Price, 'a great parliamentarian,' and her chaplain, Goode, who stole some of his papers. The commission of array granted to Crispe was reversed, and his friends are still in doubt as to the explanation as having happened through an accident, and Waller always denied that he knew anything of Crispe's scheme.

In other respects his confessions were ample enough. 'Waller,' says Clarendon, 'was so confounded with his own shame, that he could recover his understanding.' After he appeared to be in a more composed state, he was brought to the bar of the House of Commons, on the 4th of July, and there delivered a speech, which is printed in his Works, and which certainly indicates nothing like a sincere repentance. He was committed to the Marshalsea, and there he was confined till he died; and some others had their estates confiscated, and were long detained in confinement. Others made their escape to the king at Oxford. As for Waller, undoubtedly the prime contriver and agent in this, whether confined or not, his life was saved, but the facts connected with his deliverance are variously related. In the Life prefixed to his Works it is expressly asserted that he was arrested at Gunwharf, on the 4th of March, and that he only confessed to the murder of Mr. C. Waller, was kept in prison till he died; and some others had their estates confiscated, and were long detained in confinement. Others made their escape to the king at Oxford. As for Waller, undoubtedly the prime contriver and agent in this, whether confined or not, his life was saved, but the facts connected with his deliverance are variously related. In the Life prefixed to his Works it is expressly asserted that he was arrested at Gunwharf, on the 4th of March, and that he only confessed to the murder of Mr. C. Waller, was kept in prison till he died; and some others had their estates confiscated, and were long detained in confinement. Others made their escape to the king at Oxford.
nothing is recorded; nor of the eighth any thing more than her name, Octavia, given to her from her place in the list.

The merits of Waller as a poet have been elaborately discussed by Johnson. He will scarcely be now admitted to have been on his own day what he is called by the writer of his life in the 'Biographia Britannica,' 'the most celebrated lyric poet that England has ever produced,' unless perhaps we are to consider a lyric poet as meaning a poet who writes nothing but lyrics, and then the title would not be applicable to Waller. He was certainly, in so far as respects dictation and versification, the most correct poetical writer that we had before Pope; and it cannot be questioned that his example had considerable effect in the form and matter of the many hours of our poetry, although it may also have helped somewhat to tame its spirit. Yet, although there is not much glow of imagination in Waller, there is often a great deal more than mere prettiness or even elegance; his more serious pieces have of dignity and elevation of thought, as well as of expression. And generally his language has the high merit of being a most lucid mirror and exponent of his meaning, giving out with perfect distinctness at least the lines and formal features of the idea, however little it may be in the power of reflecting colour, light, or rather, however little of that there may be for it to reflect.

WALLICHA, a genus of plants named in honour of Dr. Wallich, superintendent of the Long Island Botanic Garden at Calcutta. This genus belongs to the natural order Buttericeraceae, and has the following characters:—Involucel 3-4 leaved, distant from the flower, and small. The calyx 4-parted, with oblong linear lobes. The corolla:—The tube spreading, reflexed, with thick villous claws. The stamens monodelphous, about 20; outer ones shortest. The ovary ovate, 8-celled, with single style and 8 stigmas. The fruit capsular, 8-celled, 8-valved, and a single seed in each cell. The annual and biennial, the plants a beautiful tall trees, attaining a height of 30 or 40 feet. It is a native of Nepal. It may be grown in a mixture of loam, peat, and sand, and may be propagated by cuttings.

WALLINGFORD, a parliamentary borough on the right or south bank of the Thames, in 6 miles from Oxford, in the county of Berkshire, 49 miles from the General Post Office, London, by coach-road through Brentford, Colnbrook, Maidenhead, Henley, and Nettlebed; or about 53 miles by the Great Western Railway, which passes within about two miles of the town.

There is reason to think that Wallingford existed in the time of the Romans, coins having been dug up here, and the form of the ramparts (not of the castle, which is of later origin) indicating that they have been traced by the Roman road, and the site of Wallingford in A.D. 1006, when it was taken by the Danes. The name of the place is variously spelled in ancient writers. In 'Domesday' it is called Wallingfords, and is described as a town with 30 acres of land and 46 houses. The church held, which is the present one, houses, paying gable-tax to the crown: the tenants were bound to render personal service to the king.

There was a castle here at the time of the Conquest, belonging to Wigod, a Saxon noble, who invited William the Conqueror, after the battle of Hastings, to come to Wallingford, where William received the homage of Archbishop Stigand and the principal nobles before marching to London. About a year after (A.D. 1067) Robert D'Oyley, a Norman baron, who had married Wigod's only daughter, built a strong castle here, but whether on the site of Wallingford castle or not is not clear. In the civil war of Stephen this castle was held for the Empress Maud by Brian Fitzcount, to whom it then belonged. Stephen besieged it without success several times, and here the Empress found refuge after the battle of Evesham. After her defeat, Oxford, by order of Maud, besieged a fort which Stephen had erected at Crowmarsh, on the opposite side of the Thames; and Stephen coming to its relief, a peace was concluded between the rival parties, which gave some respite to the long-disturbed kingdom. During the imprisonment of Richard I. Wallingford Castle was occupied by his brother John, but was taken from him by the king's party. In the troubles of John's reign one or two meetings of the king and barons were held at Wallingford, and III. (A.D. 1264) Prince Edward, the king's son (afterwards Edward I.), Prince Henry his nephew, and Richard, King of the Romans, his brother, were confined for a time in the castle. The castle was twice besieged in the troubles of the reign of Edward II. In Leiland's time it had a good deal to do with both by and Cameron de Cameron having a double wall, and Cameron speaks of the citadel; or keep, as standing on a high mound. In the civil war of Charles I. it was repaired and garrisoned for the king, and was regarded as a post of importance; it was set on fire by Fairfax, who surrendered to Fairfax, and was afterwards demolished so effectually, that, except part of the wall toward the river, scarcely any part of the buildings remains: the mound on which the keep stood is overgrown with trees.

Within the limits of the town are the ruins of a hospice, the church of which was attached to the priory of Wallingford, and the priory itself, in Henry III.

The borough of Wallingford comprehends the following parishes:—

The returns are from the census of 1831: about one-seventh of the population was agricultural, and only four men were employed in manufactures. The population of the borough in 1821 was 2093, so that the increase in ten years was 476, or nearly 24 per cent., a considerable increase for a town in a quiet agricultural district. The pretence of the castle is incorrectly given in the census as within the borough. The population of Crowmarsh Street, which is on the opposite side of the Thames, in the parishes of Crowmarsh and Newnham Murren, Oxfordshire, and which may be regarded as a suburb, was about 100 (one nineteen houses), bringing the population of the town and suburbs to about 3000.

The town stands in the eastern part of the area included in the boundaries of the borough, on the right or south bank of the Thames, about 1 mile distant from the stone bridge, and has about 60 houses, paying gable-tax to the crown. The town was incorporated by charter in 1646, in which it had sustained great injury: it retains some portions of Norman architecture. St. Peter's was also ruined in the siege, and remains in ruins more than a century: it has a spire of very singular form, erected in the expense of Sir William Blackstone, in the year 1646, in which the church was restored from its ruined condition. Sir W. Blackstone is buried in the church. There are meeting-houses for Independents, Baptists, Methodists, and Quakers. The chief trade of the town is in cloth, flax, malt, and coal; maltasting is not extensively carried on as formerly.
Wallington is a borough by prescription, and has sent representatives to parliament since the time of Edward I.; they were returned by the inhabitants paying scot and lot. Thirteen meetings were returned for it, one of which was returned for the Royal Society: but we do not hear of any particular attention to mathematics on his part till 1647, when he met with Oughtred’s ‘Clavis,’ at which time he says he was a very young algebraist, being then more than thirty years old. He had a writer who was a partner of the same name, and lived at Castletown, on the island of Man; they were perhaps more of the same celebrity, that they showed no strong tendency to mathematical pursuits at a very early age. When the Independents began to prevail, Wallis was one of the clergy in opposing them; and in 1648 subscribed a remonstrance against Charles I. He was then rector of St. Martin’s Church in Ironmonger Lane, but in 1649 he was appointed Savilian professor of geometry at Oxford by the Parliamentary visitors, his predecessor, Dr. Turner, having been ejected. He next removed to Oxford, and applied himself diligently to mathematics. In 1650 appeared his Animadversions on the celebrated Richard Baxter’s ‘Aphorisms of Justification and the Covenant,’ a moderate piece of theological controversy, undertaken, Wallis supposes, at the desire of Baxter himself. At the end of 1650 he first met with the method of indivisibles in the writings of Torricelli, and from this time the researches begin, of which we shall presently have to speak. In 1653 he published, in Latin, an English grammar, in which he undertook the improvement of articulate sounds prefixed. In the same year he deposited in the Bodleian Library a collection of deepened letters, which afterwards caused some trouble to the librarians. In 1654 Wallis was called to the degree of divinity, and in the following year published his ‘Arithmetica Infinitorum,’ with a treatise on Conic Sections prefixed. In 1655 he began his controversy with Hobbes, who, in his ‘Elementorum Philosophiae Secund Prima,’ had tried to reduce geometry to a tract entituled ‘Enchusus Geometriae Hobianae.’ Hobbes replied in ‘Six Lessons to the Professor of Mathematics at Oxford,’ on which Wallis published ‘Due Correction for Mr. Hobbes, or School Discipline for not saying his Lesson First.’ Oxford, 1657. Hobbes, however, published his ‘The Marks of the absurd Geometry, &c. of Dr. Wallis,’ London, 1657. Wallis answered in ‘Hobbiani Punctis Disputacio, in answer to Mr. Hobbes’s Tractatus, Oxford, 1657.’ The controversy was renewed by Mr. Hobbes in 1658, in ‘Examinatio et Emendatio Mathematicorum Hodermans,’ to which Wallis replied in ‘Hobbius Heautontimoromenos, Oxford, 1658.’ Wallis, as may be supposed, had the right on his side; and we are disposed to regret that a dispute of this kind should have arisen, and that this man, in the collection of his works, though we cannot but respect the motive, namely, the desire not to attack an opponent after his death. In 1656 he published his treatise on the angle of contact, and a defence of it in 1658.

Wallis was of the school of the English mathematicians, and in 1658 appeared, under the title of ‘Commercium Epistolicum,’ a correspondence arising out of a question proposed to him by Fermat: also a sermon, ‘Mens sobria accuratissima, and a commentary on the Epistle to Titus. In 1658 the questions of Pascal on the cycloid appeared, which were answered by Wallis, and led to a controversy. About this time Wallis, who with others desired the restoration of the king’s power, employed his art of deciphering to the side of the royalists, so that at the Restoration he was received with favour by Charles II., confirmed in his professorship, and in the place of keeper of the archives at Oxford, and was made one of the royal chaplains. In 1661 he was one of the clergy desired to return to the restored Court of Henry VII., and was one of course one of the first members of the Royal Society, and from this to his death his life is little more than the list of his works. His tract on the Cono-cuneus, or circular wedge, was published in 1669; his treatise on the use of the cycloid in collision, in the same year; his new hypothesis on the tide, ’De Zeten Mariis,’ in 1668; and the treatise on mechanics at different times, in 1668, 1670, and 1671. In 1673 he edited the works of Oughtred, the first of which is on the subject of the cycloid, and appeared in 1676; his edition of Ptolemy’s Harmonics (to which other antient mathematicians were afterwards added) in 1680. His algebra appeared in English in 1685, and was translated into Latin with additions in the collection of

Vol. XXVII.-G

P. C., No. 1686. given a succinct account of the proceedings of this body. (See the Biographia Britannica.) In this year also he married. In 1645 he was among the first who joined the project of founding the Royal Society, and was appointed to two from one. The boundaries of the borough were enlarged by the Boundary Act, by the addition of the parishes of Brightwell, Sotwell, North Moreton, South Moreton, Burnham in Close, Greenaw, and Newnham Murren; the liberty of Clapcott, and the three extra-parochial chapels of Hambleden,arges, and Castley; and part of the parishes of Cholsey, Aston-Tirrel, and Aston-Uphorpe. By these additions the number of houses and the population of the borough were nearly doubled. This act was renewed by the Reform Act in 1643, 1649, 1653, 1661, and 1671. From the act of 1661 to 1680. By the Municipal Reform Act the borough has 4 aldermen and 12 councillors, but no commission of the peace, except on petition and grant. The municipal boundary was not altered by that act; but a more extended coast of extending the Castle precinct, which was removed to Oxford, and applied himself diligently to mathematics. In 1650 appeared his Animadversions on the celebrated Richard Baxter’s ‘Aphorisms of Justification and the Covenant,’ a moderate piece of theological controversy, undertaken, Wallis supposes, at the desire of Baxter himself. At the end of 1650 he first met with the method of indivisibles in the writings of Torricelli, and from this time the researches begin, of which we shall presently have to speak. P. C., No. 1686.
his works: in the same year also, his treatise on Angular Sections and on the Cune-cuneus. In 1685 he wrote theological pieces on Melchisedec, Job, and the titles of the Psalms. In 1687 appeared his celebrated work on loge. In 1688 he edited Archimedes and fragments of Pappus. In 1689 he published his pieces on the Trinity, and on the baptism of infants; and, in 1692, his defence of the Christian baptism against the Sabbatarians, or observers of Saturday. The collection of his works by the curators of the University press began to be made in 1693; the three volumes of the first series appeared in 1693, 1694, and 1695.

In 1692 he was consulted upon the adoption of the Gregorian calendar, or new style, against which he gave a strong opinion, and the design was abandoned. In 1694, when the first two volumes of his works appeared, he was appointed reader in mathematics, beginning the following year with the followers of Newton and Leibnitz. Some remarks were made on his assertions as to the origin of the differential calculus in the Leipsic Acts, which produced a correspondence, and this correspondence was published in the third volume.

He died October 28, 1703, in his 88th year. The character of Wallis as a man was attacked upon one occasion only, in which it was asserted that he had deciphered the king's letters after the battle of Naseby, to the disadvantage of his majesty and his royal cause.

It was also said that the collection of deciphered letters which he gave to the University had some of its contents withdrawn by him when the Restoration was approaching. Wallis himself denied that he had deciphered the king's letters; and, though he granted his adherence to the parliament to be justifiable, he had been no more than his duty. A sort of repugnance exists to a decipherer, though common sense tells us that those who intercept and open an enemy's letter which, being deciphered, is transformed into language which is added to those into whose hands it may fall, are much more obnoxious to any charge than the decipherer of a letter which, being written in cipher, more resembles a defiance.

All that can be said against Wallis, if it amounts to anything, is, that when at one time and under very different circumstances, he wanted the restoration, he used his talents for it. And as to the charge of withdrawing the letters from the Bodleian, it ought to have been added, that when he presented them, it was with a written reservation to add or withdraw. The best testimony to the general character of Wallis is as follows:—He was exceedingly obnoxious to the high church party, and entirely from his love to the ministry, from his having been forced upon the University by external and democratic power. But all that his contemporary Wood, who will not admit him into the 'Athenius Oxoniensis,' as an Oxford writer, can say or hint against him, is much as well as the most remarkable, and yet there was no want of disposition to disapprove a Presbyterian in Wood, as witness the following liberal sentiment:—'The senior proctor, according to his usual perjury (which he frequently used in his office, for he was born and bred a Presbyterian), did pronounce,' &c. &c. (Ath. Oxon., ii. 1045.)

Wallis, in his literary character, is to be considered as a theologian, a scholar, and a mathematician. As a divine, he would probably not have been remembered, but for his eminence as a mathematician. The other characters—literary, religious, and trigonometrical—are still quoted in the histories of opinions on that subject. At the time of South and Sherlock, much was written on the Athenian Creed which was meant to be of an explanatory character: those who read South and Sherlock, and those who have the charter of the Trinity, may also have found to be neither; but many have considered him scarcely orthodox. If the character of Wallis has been elevated as a divine by his celebrity as a philosopher, his service has a so much the more reason, for the same reason, that of not valuing the illuminations of the editor of Ptolemy's Harmonics, of the commentary on it by Porphyrius, and of the later work of Briennius; as also of

* Such volume ought to have a portrait, those of the two first with a skull; and a frontispiece, that of the last with a flowing wig, and the book of a syllem: but both the portraiture and the frontispiece were very like that of the coat of arms appended. The first volume has a double title page, one for each of the two volumes (1693).

It has been suggested that, as Charle's private cabinet was taken at Naseby, in all probability the key of the cipher was taken with the letters, but in one day it would be asked what it mattered whether the letters which Wallis deciphered were those of Charle, or of his generals and ministers.
ology will not yet take its place, under definitions, by the side of the latter.

Of the several generalizations, in which Wallis was superior to any preceding mathematician, enabled him to avail himself of ideas which the ordinary processes of arithmetical and algebraic methods had offered for centuries without results. Having, by his use of fractional indices, been able to supply every case of $a^{x} b$, or an equivalent result, it struck him that $f^x g^x$, still using modern symbols, must be capable of a similar interpolation. The case of $a^x + b$ obviously gives the circle, and after making various attempts in this direction he was able to present the well-known result, which is still remembered by the name Wallis; but the method which produced it, is, though anything but forgotten, not always duly remembered as belonging to Wallis. This result is as follows, in modern terms:—

$$\left(\frac{a}{b}\right)^{x} \cdot \left(\frac{c}{d}\right)^{x} = \left(\frac{a}{b} \cdot \frac{c}{d}\right)^{x}$$

for all values of $x$. It is often expressed thus:

$$\frac{a}{b} \cdot \frac{c}{d} = \frac{a \cdot c}{b \cdot d}$$

The works of Wallis contain many other results which may be considered as advanced specimens of the integral calculus in every direction. The most remarkable of these is the solution of the parabolic, which he showed to depend upon the quadrature of the hyperbola. The Binomial Theorem was a corollary of the results of Wallis on the quadrature of curves, the sagacity of Newton supplying that general mode of expression which it is extraordinary that Wallis should have missed.

We have not spoken of the work on logic, which is not only of the highest excellence, but is perhaps, owing to the recent methods in modern mathematics, the only work of Wallis on the subject which we could now recommend a student to read. In conclusion we may say of the subject of this article, that it rarely happens that there is so singular a union of originality and labour.

WALLIS, SAMUEL, the first navigator after Quiros (assuming that Quiros's Sagittaria is Tahiti) who discovered the island of Tahiti. The date of Wallis's birth and his parentage are unknown. In 1756 he was lieutenant of the Gipsy Queen, and six years after was put into command of the twenty-four gun ship,which he was promoted to be lieutenant of the Torbay seventy-four, Vice-Admiral Boscawen's flag-ship. On the 8th of April, 1777, he received his commission as captain of the Port Mahon, of twenty guns, and was sent to North America with Holbrook as his warrant officer. In 1760 he was appointed to be lieutenant of the Island with the 1760 '29 W. long. It received its name from Capt. Wallis, who discovered it on the 15th of December, 1767. It is five to six miles from north to south, but it is not much more than half these dimensions in width. The interior of the island is rather high, but along the shore it is low and rocky. The island is surrounded by a reef, in which a break occurs on the west side, with which he was commissioned to break a vessel may anchor in sight fathoms water. The reefs are from two to three miles from the shore. The island is covered with trees to the water's edge, and many of them are of large size. In some parts there are plantations of cocoa-nuts. There are several species of fish in the island. The inhabitants go naked, except that they wrap a kind of mat round their middle. They are armed with maces or clubs; but Capt. Wallis, the only navigator who has visited this island, had no intercourse with the natives.

(Hawkesworth's Account of the Voyages undertakenn for making Discoveries in the Southern Hemisphere, vol. 1.)

WALMESLEY, CHARLES, an English mathematician and astronomer, was born in the year 1724. Being a member of the Roman Catholic church, he became a monk of the Benedictine order in this country, and he took the degree of doctor in theology in the Sorbonne. In 1750 he was elected a Fellow of the Royal Society of London, and was made archbishop and apostolic vicar of the western district of England.

His principal work, which is an extension of the 'Harmonia Mensuralum' of Cotes, is entitled 'Analyse des Mesures des Rapports et des Angles, ou Réduction des Angles Premiers aux Angles de la Chordale.' It was published in Paris, 1749; in the same year he published his 'Théorie du Mouvement des Apsides,' 8vo., and in 1758 the treatise 'De Inequalitatis Motum Lunaria,' 4to., Florence.

Dr. Walmesley was one of the mathematicians employed in regulating the calendar in this country, preparatory to the change of the style, which took place in 1752, and he wrote several papers on astronomical subjects, which were published in the 'Philosophical Transactions.' As a theological writer he is known only by his productions, and explanations of the Apocalypse, Ezekiel's vision, &c. He died at Bath, in the 76th year of his age.

WALNUT-TREE, the common name of the species of Juglans, a genus of plants belonging to the natural order Juglandes. The nuts are large, oblong-obovate in form, and enclosed in a hard, thick, leathery shell. The flowers are unisexual, and those containing the stamens and pistils are found on the same tree. The staminate flowers are arranged in cylindrical drooping solitary catkins, which are developed from buds borne on the shoots previous to that in which the catkin appears. The stamen is composed of 5 or 6 scales, which are attached to a bract or bracteate scale. The stamens are from 18 to 56 in number. The pistillate flowers are solitary, or group together in a group, and are terminated by a shoot developed in the same year. The calyx is ovate, including the ovary, and adhering to it, except at the four-toothed tip. The petals are 4 small, and inserted into the free part of the calyx. The fruit has one cell.
and one erect ovule. The stigmas are two or three, and fleshy, scaly with glands. The fruit a drupe. The covering of the nut is a fleshy husk of one-piece, that bursts immediately it is woody. It is a very common fruit of two varieties.

The species Carya, three of which are natives of North America and one of Asia. The genus Carya, to which the hickory-trees belong, was formerly included under Juglas, but was separated by Bentham as the species of Juglas are much more rapid in their growth than those of Carya, and are furnished with only simple aments.

The Royal or Common Walnut-tree (Juglas Regia) is the oldest and best known of the species. Its leaves are red or crimson in spring, and of a bright green, shining, or serried leaflets. The fruit is oval and seated on a short inflexed peduncle. The nut is rather oval, and uneven. It is a native of Persia, in the province of Ghilan on the Caspian Sea. It has been also seen by Loureiro in the north of China, and Pallas, who saw it in Russia and south of the Caucasus, supposed it indigenous there.

The walnut-tree was known to the Greeks under the name of Persicon, Basileon, and Caryon. It is uncertain at what time it was first cultivated by the Romans before the death of the emperor Tiberius. Its wood was much valued by the Romans, and the nuts were also eaten. There is no history of the introduction of this tree into Great Britain, but it is now very generally cultivated in the nursery trade, although efforts are being made to propagate it by itself. Its seeds. It is only however in the southern and middle parts of England that the walnut brings its fruit to perfection.

The walnut, when full-grown, is a large handsome tree with spreading branches. Its trunk is thick and massive, and covered with a deep furrowed bark; the branches are of a grey colour, and smooth. The leaves, when bruised, give out a very peculiar aromatic odour, and in the heat of summer this scent is sometimes so powerful as to have a pleasant effect on the sense of smell. The foliage is graceful and light, and of a bright yellowish green colour, which contrasts well with trees having foliage of a darker shade. Its leaves are oblong, entire, acuminate at the apex, and round at the base; they grow very rapidly and vigorously in the climate of London, and trees will attain a height of 20 feet in ten years. It sends down into the earth a large tap-root, with numerous branches, and, on account of the size and strength of the root, the soil is no longer subject to erosion. The effects of wind, or better adapted for exposed situations. It is said that plants will not grow under its shade; this probably arises from the bitter properties of its leaves: when they are not allowed to accumulate, the shade of the walnut does not appear so injurious as that of other trees. The walnut-trees may be planted at any time they are easily transplanted; the heat of the summer being a means which will not injure them, and then exposed to dry for a day or two in the sun. The best mode of keeping the nuts fresh for eating is to bury them in dry soil or sand, so deep as not to be reached by frost. The best way of gathering them is to scoop out the meat, which is done in dry cellars and covered with straw. When the nut is to be preserved through the winter for the purpose of planting in the following spring, it should be laid in a ret heat as soon as gathered, with the husk on; a small heap should be kept over frequently in the course of the winter.' (Loudon.)

The albumen which constitutes the bulk of the seed of the walnut contains an oil, which is used in large quantities especially on the Continent. It is obtained by reducing the oil-seeds, which must be being liable to rapidity with the wood with great care in keeping, as it becomes tainted by slight changes in the state of the atmosphere. That which is cold-drawn from the seed, and subsequently refined, is the most preferable.

It has however always the taste of the walnut, which is to some persons disagreeable. The oil obtained by heat is used by artists, and also for lamps. Artists use this oil in mixture with white, or any delicate colour; they paint their scent, and for general printing also. In Paris, walnut-oil is considered indispensably necessary in order to obtain a fine impression, whether in black or in colours. For this purpose they use the timber of the walnut from France, and the colour with which it is to be mixed. In all cases it is reduced in bulk by boiling or by setting fire to it, so as to reduce it to the required consistency. One bushel of nuts, it is said.
will yield about seven pounds of this oil. The mass which is thus made is exposed to the sun, air, and rain, and used as food for swine, sheep, and poultry, and in some places it is made into candles, which give a tolerably good flame.

The husks and root of the walnut both yield a dye which is much used by gypsies and theatrical performers for staining the skin brown. It is also used by cabinet-makers and joiners to stain white and yellow woods of a dark brown or black colour, like that of the walnut. In the preparation of the dye from the husks they should be allowed to remain a week in the country. It is by distilling to the decoction fresh water, according to the colour required to be produced by the solution. The sap of the walnut-tree contains a large quantity of saccharine matter; and in some countries the trees are tapped for the purpose of supplying it as a sugar. There is also in many parts of Europe and Asia fermented and made into wine, and a spirit is also distilled from it. The leaves of the walnut, as well as other parts of the tree, contain a large proportion of alkaloids, and in some parts of France they are collected and burned for the sake of the potassa contained in the ashes.

The bark of the leaves, the husks, and the oil of the walnut have all been used in medicine, and had at one time, and perhaps are still, extensively employed for that purpose. The albumen of the seed, possess a bitter principle, which acts as a tonic and an anthelmintic, and has been its great recommendation as a medicine. Cowley, in his 'Plants,' sums up the virtues of the walnut in the following lines:

"One of the most useful plants that grow.
Her timber is for various uses good.
The currer she supplies with liberal wood.
Her leaves supply the painter with glowing colours last.
A table she affords us, and repast.
Every part of her is a useful supply.
The most potent of all is the virtue she deadens with the shooting of raging skyes.
The Festival king, who lived where poisons grew,
Shin'd in antimony, her virtues knew."

Anglers employ an infusion of the leaves or husks for procuring worms, which, when speedily brought to the surface, will quickly arise to the sight of the worm. There are several distinct varieties of the walnut cultivated. The maximus is known by the large size of its nuts, and is called the double large French. The nuts are twice as large as others; but in drying, the kernels shrink to half their size, so that they ought to be eaten as soon as they are gathered. This is a fine handsome tree with large leaves, but its timber is not so durable as that of the common walnut. The thin-shelled or Tintomace Walnut (J. f. tenera) has very thin shells, so much so that birds of the Tintomace family pierce them with their bills and eat the kernel. The fruit of this variety is considered the best for eating, and it also yields the largest quantity of oil. It is still more valuable in a manufacturing point of view, as it is a variety of great desirability in districts where the frosts are severe in spring. Its leaves do not appear before the end of June, and it ripens its fruit as early as the other varieties. There is a variety known in Norfolk and Suffolk by the name of the Highflyer, which is said to yield the best nuts of any of the English varieties. Several other varieties are enumerated in continental lists; and in the Fruit Catalogue of the Horticultural Society for 1832, nine varieties were recorded as growing in the gardens of the Society.

The Black Walnut-tree (Juglans nigra) has leaves with from 13 to 17 leaflets, which are unequal at the base, serrated, and somewhat downy. The fruit is globose, roughish, with minute prominent points, situated upon a short peduncle. The nut is globular, somewhat compressed at the sides, ridged, and furrowed. This is a North American tree, and is found in all parts of the United States, as far as 40° 50' N. lat. It is abundant in the forests about Philadelphia, and is met with from Georgia to Michigan. The gas is plentiful in the north of England, and is obtained in the eastern states of America in an extent of 2000 miles. It is one of the first trees that was introduced from America to Europe, having been brought to England by the younger Tradescant in 1656. The black walnut is a remarkable tree, and attains a height of 60 or 70 feet in about 40 years. It bears fruit in this country, but it is very much inferior to that of the European walnut. The wood of this tree is used almost for the same purposes as that of the last. It is heavier, stronger, susceptible of a finer polish than the European species, and is not so liable to be attacked by worms.

The Gorse Walnut or Butternut Tree (Juglans cinerea) has 15 to 17 leaflets, rounded at the base, serrate, and tomentose beneath. The petiole villous. The fruit is ovate with a taper tip, downy, and covered with small transparent vesicles containing a viscid matter. The nut is oval, with very prominent irregular ridges. This tree is from North America. It is found in the United Lakes and in the temperate regions of the United States. This tree attains in its native regions a height of about 50 or 60 feet. Although it was introduced into this country about the same time as the last species, there are very few large specimens of it. It is chiefly used for the purpose of fuel, and soon becomes rancid, and hence probably the names of butter-nut and oil-nut. The wood is used in the districts where it grows for the same purposes as the last. Its bark contains considerable medicinal powers, and is used in the United States as a purgative, and for the cure of toothache.

It's leaves also are so aerd, that they are employed, when powdered, as a substitute for antimonials.

All the species of Walnuts are best propagated by the seed, which, when the tree is intended for ornamental timber, should be sown in the place where it is wished it should remain, as the large tap-root of these trees is likely to be injured by removing them, although with great care they may be successfully transplanted. When trees are to be grown for the purpose of obtaining their oil, the growth is increased by budding, grafting, and sometimes by layering.

The most approved successful mode of budding, and which is the one chiefly adopted on the Continent, is that with the flute method, in which an entire ring of bark, containing one quarter, is cut out and fixed to the upper extremity of the stock, which is also denuded of its bark; should the stock be larger than the ring containing the buds, the ring requires to be slit up, but if this extends the stock, a small portion requires to be cut off so as to make it fit. Mr. Knight also invariably succeeded in budding the walnut by using the minute buds that are found at the base of the annual shoots of this tree, which, as he says, "are almost concealed in the bark, and is barely seen. The practice is, however, to cut and cement the vascular bundle of the bud to the stock, by the use of the insertion of the large prominent buds which occupy the middle and opposite ends of the annual wood." (Selby.)

These he inserted on yearly stocks which grew in pots, the vegetation of which had been retarded by exposing them during the spring and early part of the summer in a northern aspect, until the above-mentioned buds were formed on the current year's shoots of the trees intended to be propagated, when the pots containing the young plants were brought into a forcing-house and there budded. There is no tree that requires less pruning than the walnut, and where large branches are cut off, it is almost invariably followed by a decay of the tree at the spot where abscission was performed. The best soil for the walnut is a light sandy loam, without manure, and almost anywhere, provided the soil is free from stagnant moisture. The best fruit is obtained from trees growing on calcareous soils.

Previous to the time of the publication of Nuttall's 'Genera of North American Plants,' the various species of North American trees called hickory were regarded as species of the genus Juglans. These Nuttall referred to a new genus, Carya. (Carya.) There is another species, formerly referred to Carya, and called J. flexuosa, which Kunth has made into a genus called Pterocarya. It differs from Juglans in its fruit having two wings, and in the embryo not being accompanied by albumen. It is a native of moist woods at the foot of the Caucasus, and hence called P. caucasica. It is a small tree with an ample bushy head, attaining a height of 30 or 40 feet. Its leaves are alternate, very large, commonly having 19 leaflets, which are oblong, deutilculate, with blunt teeth. Each of the leaflets has on the sides short teeth or papillae.

The term 'Ludlow's Arb. et Frut.' Brit. & Ireland, Michaux, North Amer. Sylva: Encyclopædia of Gardening' was published in 1832, and the text appears to be a collection of information about various species of plants, including walnuts and hickories.
W A L

Anne, had been notorious; and apart from political expediency, it became the duty of the ministers of the late king of the House of Hanover to denounce, and, if possible, extinguish the faction that had nearly succeeded in altering the succession to the throne. Walpole drew up the report on which the impeachment and trial of Sacheverel was decided. The preceding time brought on a severe illness. Before his recovery the memorable Septennial Bill, which had been prepared with his concurrence, was passed. It was perhaps scarcely justifiable on constitutional grounds to proceed with the impeachment during the summer. However, it was passed, and, as a protest against this procedure, he took a leading part in all the proceedings. The rebellion in favour of the Pretender soon afterwards broke out, in the midst of which Walpole was appointed first lord of the treasury and chancellor of the exchequer. He had not been long in the country when, in July, 1715, he retired to Chelsea, where he soon took up his residence. There he was kept in the utmost ignorance of all public events, and the Whigs in the meantime continued in power. He was roundly called a Jacobite, and once engaged in business with much activity, and joined the Whigs in promoting the Protestant succession. Although his first attempt at oratory does not appear to have been very successful, he soon displayed his ability as an able and practical debater and an acute politician. He attracted the attention of the great leaders of the Whig party; and in March, 1705, when their influence had risen in parliament and in the cabinet, he was appointed one of the council to Prince George of Denmark, the Lord High Admiral. In this capacity he showed much prudence and firmness under peculiar difficulties, that he won the esteem and confidence of Godolphin and the Duke of Marlborough. Henceforward he assumed a high position in politics. In 1708, on the death of the Whig secretary-at-war, the management of the House of Commons was entrusted to him by his party. In 1710 he was appointed one of the managers for the impeachment of Sacheverel. He had strongly opposed that proceeding in public controversy, but had been driven by the necessity of conducting it chiefly devolved upon him. He afterwards published a pamphlet, entitled "Four Letters to a Friend in North Britain upon the publishing of the Trial of Dr. Sacheverel." In which he laboured with the utmost talents and influence, that he vainly endeavoured to persuade him to accept a place in the new administration, and declared him to be worth half his party. Party spirit was then most virulent, and in order to crush their opponents the Tory government under Harley and St. John charged the ex-ministers with extensive corruption and inaccuracy in the public accounts. The defence of his colleagues was ably conducted by Walpole; but he was punished for his zeal on their behalf, by a similar accusation against himself published in the form of a pamphlet. On January 1712, a majority of the House resolved that while secretary-at-war he had been 'guilty of a high breach of trust and notorious corruption,' and that he should be committed to the Tower and expelled the House of Commons. He refused to manifest any submission, and remained a prisoner in the Tower until the prorogation. Meanwhile his friends looked upon him as a martyr to their cause, and flockcd to his apartments, which bode, it is said, the appearance of a crowded levée, rather than of a prison. He was re-elected for Lynn; but (in accordance with a doctrine afterwards declared illegal in the case of Wilkes) was declared incapable of sitting in that parliament. He did more for his vindication with his pen while in prison, than he could have done in the face of his enemies, who had already condemned him. A pamphlet published by him at that time was declared by his party to be a complete refutation of the charges affecting his character. Whether this be so or not, his exertions added to his distress and not unlike increased his influence. At the dissolution, in August, 1713, he again entered parliament as member for Lynn, and took a distinguished part in all the debates and in the proceedings of the investigation of the irregularities and corruptions of his party. On the accession of George II., Walpole, with his brother-in-law Viscount Townshend, had a principal share in the formation of the Whig administration. He was himself appointed paymaster-general of the forces and of the land office. The disunion of 1715 having formed a large majority for the Whig ministry, they had an opportunity of averting themselves for the prosecution they had suffered from their predecessors in office. The intrigues of many of the leading Tories in favour of the Pretender during the last four years of the reign of Queen
was created a Knight of the Bath, and in 1726 was installed a Knight of the Garter. But though strong in parliament, and standing well with the king, Walpole was continually in danger from the intrigues of the court. On the accession of George II., however, Walpole was so fortunate as to find a protector in Queen Caroline, whose influence and successes of his first years in office, although a change had been determined upon, and afterwards to support him against the persevering machinations of all parties.

To follow Sir Robert Walpole through the events of his long career, and not require little less than a history of his times. There were no important debates in parliament, no deliberations in the cabinet, no negotiations with foreign states, in which he did not bear the most considerable part from the first day of his administration. The most remarkable measure proposed by him was one that caused perhaps the most contempt to his talents as the minister of a commercial country, was his Excise scheme, brought forward by him in 1733. The object of this measure was to convert the Customs duties payable upon certain articles of import immediately on their arrival in port, into Excise duties payable on taking them out of warehouses, for home consumption. He also proposed to confine the taxed commodities to a few articles of general consumption, and to exempt from the Excise all the necessaries of life and all the raw materials of manufacture. The plan itself and the arguments by which he supported it prove the soundness of his views of taxation and commerce; but unhappily the measure was artfully misrepresented as a scheme to burden the people, and was opposed by the able writers opposed to the minister, by the clamours of those interested in existing abuses, but more than all by the unpopular name of 'Excise,' were almost unanimous in its condemnation. Public feeling became at length so strong, on both sides, that it seemed by threaten any further progress with the bill; and Sir Robert was very reluctantly obliged to abandon it. He was fully persuaded of its great advantages to the country, but said, 'I will not be the minister to enforce taxes at the expense of public comfort.'

In 1737 the influence of Walpole was much shaken, first by the quarrel between the king and the Prince of Wales, and the avowed hostility of the latter to the king's government, and especially to Walpole, who had been chiefly consulted by the king; and, secondly, by the death of Queen Caroline. The high regard of the queen for Walpole was testified even on her death-bed. Turning to the minister, with whom the queen was standing by her bedside, he said: 'He who was the king's constant minister, but continue to serve him with your usual fidelity,' and addressing to the king, she added, 'I recommend his majesty to you.' Shortly afterwards the king showed Walpole an intercepted letter, in which it was affirmed that the minister had been seduced from his professions. It is false, said he; 'you remember that on her death-bed, the queen recommended me to you.'

Walpole was soon in the midst of great embarrassments. The king, the people, a strong minority in the Commons, a majority in the Lords, a popular outbreak in the cabinet, were eager for war with Spain. Walpole endeavoured to avert it as a national calamity, but was overpowered by the union of so many parties in its favour. He then felt how much his popularity had suffered from his opposition to them or domestic, during the last two years. It was unjust to his charge. He entreated the permission of the king to resign, but his majesty exclaimed, 'Will you desert me in my greatest difficulties?' and refused to accept his resignation. In the midst of the discussions upon the Spanish war, a motion was made for a general repeal of the Excise; and the country, beholding those talents in debate and personal influence became a serious obstacle to his measures. Discord ensued in the cabinet, and the opposition in parliament became more strenuous than ever. In February, 1740, a motion was made in the Commons, and with so much success that the motion, which was the revocation of Sir Robert Walpole from his majesty's presence and counsels for ever. No distinct charges were made against the minister to justify so strong an address; but every complaint against the measures of his government, foreign or domestic, during the last two years, was given as a reason for his dismissal. 'If it should be asked,' said Sandy, 'why I impute all these evils to one person, I reply, because one person grasped in his own hands every branch of government; that one person has attained the sole direction of affairs, monopolized all the favours of the crown, commanded the disposal of all places, pensions, titles, ribands, as well as all preterments civil, military, and ecclesiastical.' Walpole defended himself with becoming boldness and dignity, and referred with pride to his administration. The motion was carried by a large majority, and a similar motion in the House of Lords met with the same fate. But, notwithstanding this triumph, his power was nearly exhausted. A resolution immediately followed; his opponents were at the election. He himself had been indulgent of success, and on the meeting of the new parliament he found himself in a bare majority. After several close divisions, he was, on the 2nd of February, 1742, left in a minority of sixteen, on the Chippenham election. On the 9th, all events led the Earl of Orford by the king, and on the 11th he resigned. On taking leave of him the king burst into tears, expressed his regret for the loss of so faithful a counsellor, and his gratitude for his long services.

No sooner was a new administration formed under Pulteney (which, through the influence and address of Walpole, had been composed chiefly of Whigs,) than an attack was made upon the ex-minister. On the 9th of March Lord Limerick moved a committee to inquire into the administration of Sir Robert Walpole during the last twenty years, but his motion was lost by a majority of two. Lord Limerick very soon made a second motion, but proposed to include only the last ten years in his inquiry. It was defeated by a minority of seven, and a committee of secrecy was appointed. Of the twenty-one members of this committee, nominated by ballot, all except two had been Walpole's uniform opponents. The committee, failing to obtain the evidence of corruption which he had expected, endeavoured to pass a bill of indemnity to all persons who would make discoveries, but this invidious and unjust measure was rejected by the House of Lords. The committee nevertheless made a report, in which they charged Walpole—1, with having used the influence of the public service to apply grants of fraudulent contracts; and, 2, with peculation and profusion in the expenditure of the secret service money. These charges were but ill supported, and considering the clamours that had been raised against the minister, the decided enmity of the committee, and the ample means at their disposal, the report must be regarded, if not as a verdict of acquittal, at least as one of not proven. A motion for renewing the inquiry was rejected by the following week, for Sir Charles Lyttelton's motion, which was permitted to pass a bill of indemnity to all persons who would make discoveries, but this invidious and unjust measure was rejected by the House of Lords. The committee nevertheless made a report, in which they charged Walpole—1, with having used the influence of the public service to apply grants of fraudulent contracts; and, 2, with peculation and profusion in the expenditure of the secret service money. These charges were but ill supported, and considering the clamours that had been raised against the minister, the decided enmity of the committee, and the ample means at their disposal, the report must be regarded, if not as a verdict of acquittal, at least as one of not proven. A motion for renewing the inquiry was rejected by the following week, for Sir Charles Lyttelton's motion, which was sumptuous, and supported by the House of Lords, having observed to his brother that he had left his to treat with the Commons, and, as they were suffering from the stone, which be bore with admirable fortitude, he died on the 18th of March, 1745, in the sixtieth year of his age, and was buried in the parish church at Houghton.

The character of no public man has ever been more misrepresented than that of Walpole. He had the misfortune to be actively opposed by the first wits of his day. The brilliant talents of Bolingbroke, Chesterfield, Swift, and Pope filled the press with sarcasms, and mis-
courage it. The extremely difficult circumstances in which Walpole was placed by the claims of the Pretender and the unpopularity of the House of Hanover, must also be pleaded in his justification. His zeal for the Protestant succession was certainly the main principle of his political life and administration. The same great authority who vindicated him from the charge of systematic corruption thus sums up his services:—"The prudence, steadiness, and vigilance of that man, joined to the greatest possible lenity in his character and his politics, preserved the constitution and the family: and with it their laws and liberties to this country." (Burke's "Appeal from the New to the Old Whigs," p. 63.) In private life he was distinguished by his hearty good nature and social dispositions. His conversation and manners were not coarse and indelicate, but had the happy art of making friends, and great powers of persuasion. For business of all kinds he had an extraordinary capacity, and the ease with which he executed it led Lord Hervey to say, "Mr. Walpole finished the same ease and tranquillity as if he was doing nothing." (Coxe's "Memoirs of Sir Robert Walpole; Smollett's "History; Tindal's "Continuation of Rapin; "Historical Register; Political State of Great Britain; Chandler's "Life of Sir Robert Walpole, his Autobiography." "WALPOLE, HORACE (Earl of Oxford), an ingenious and accomplished writer of the last century, was the third and youngest son of Sir Robert Walpole, by Catherine Shorter, his first wife, and was born October 5th, 1717. When he had finished his education at Eton and Cambridge, he left England and travelled on the Continent for more than two years. For the greater part of this time he was accompanied by Gray, the poet, with whom he had formed a friendship at school; but a difference of political opinion arose between them, and they parted at Reggio, in July, 1741, and returned to England by different routes. On his return home in September, 1741, Walpole took his seat in the House of Commons for the time being, and was returned as a Member for Callington, for which place he had been elected during his absence. At his return, his father's administration was at that time in the midst of the difficulties which shortly afterwards caused its downfall, and he could not fail to be deeply interested in all that passed. He did not however take any prominent part in the debates. His first speech was delivered in March, 1742, on a motion for inquiring into the conduct of Sir Robert Walpole for the preceding ten years of his administration, and was favourably noticed by Mr. Pitt, afterwards Lord Chatham, and by Steele, in his "Hog of a Time." Bishop Berkeley is quoted as observing that the interest excited by his father's affairs had subdued, he was very rarely induced to address the House. He moved the address in 1751, and spoke in 1756 on the question of employing Swiss regiments in the colonies. In 1757 he expressed in a letter to his friend Mr. Pitt his sympathy with the unfortunate Admiral Byng. These are the chief events of his public life, although he remained in parliament till 1768, a period of twenty-eight years. In 1744 he had exchanged his seat for Callington for Castle Rising; and from 1744 he represented King's Lynn, the borough which had returned his father for many years to parliament. Public life was not suited to Horace Walpole's pursuits and tastes, but he was always much interested in politics. His family connection had early identified him with the Whig party, but his speculative views were more elevated, and he devoted his reverence for popular rights and his affected hatred of kings, to the engraving of the death-warrant of Charles I., and wrote upon it, "Magna Charta." He was a master in the art of abstract opinions and to lead him into any practical extravagance, for his habits and temper of mind were fastidiously aristocratic.

The principal amusement and business of Walpole for many years of his life were the building and decoration of his house at Strawberry Hill. This house was originally a small cottage, which he purchased in 1747, but grew under his hands into a so-called mansion of considerable extent. It would be difficult to compliment his taste in architecture, but the Gothic style was not at that time in vogue, and many faults and absurdities which are now apparent at Strawberry Hill must be referred to the novelty of the attempt to apply to a modern domestic residence the characteristics of an antique style. He collected works of art and curiosities of every description to ornament his house and gratify his tastes—prints, pictures, miniatures, armour, books, and manuscripts. He was enabled to indulge in these expensive pursuits by the profits of three income offices which his father had obtained for him, viz. usher of the exchequer, comptroller of the pipe, and clerk of the estreats.

To the tastes of a virtuoso he added those of a man of letters. His earliest compositions were in verse, and though many of them are sprightly and agreeable, they are not imaginative, and even but slight for versification. In 1752 he published his "Ades Wal- polei," which contains a work of great value being in fact a catalogue of his father's pictures at the family-seat of Houghton Hall in Norfolk; but, like other literary works of the same author, it was consistent with his favourite pursuits: the curious literature of the family.

In 1761 he commenced the publication of "A Catalogue of Painting in England," which were not completed until 1771; and in 1763 he added a "Catalogue of Engravers." Both these works were founded upon materials supplied by the circle of his family, and were finished with such a happy style of writing, for which he is remarkable.

Walpole's celebrated novel, the "Castle of Otranto," appeared in 1764, as a translation, by William Marshall, from the Italian of Osippphio Muralto, which the author is stated to have founded upon an incident in the life of Newby, in a new style, exciting various opinions at the time, but it was, on the whole, eminently popular and successful, and is still read with interest as one of our standard works.

In the opinion of Sir Walter Scott, the "world's most singularly entertaining and universally admired work," in his character of a historical agent with human interest, to a tone of feudal manners and language, sustained by characters strongly marked and well discriminated, and to unity of action, produces a real sensation, and a grandeur and noble simplicity, in fine, which cannot be denied to him, who can exalt the passions of fear and pity, must be awarded to the author of the "Castle of Otranto."" Lord Byron goes even further in his praise, and calls the "Castle of Otranto" the last romance in our language, and the debate on it he says was the most entertaining of all Walpole's writings. His letters, addressed to various friends, collected by himself, and published at different times since his death, Walter Scott calls him the best letter-writer in the English language, and Byron speaks of his epistolary talents as "reserved and unassuming, and must be placed upon them as an historical work, for the author's prejudices and political partialities are too open to entitle his evidence or judgment to much weight.

But the first love was not certainly the most entertaining of all Walpole's writings: his letters, addressed to various friends, collected by himself, and published at different times since his death, are the best letter-writer in the English language, and Byron speaks of his epistolary talents as "reserved and unassuming, and must be placed upon them as an historical work, for the author's prejudices and political partialities are too open to entitle his evidence or judgment to much weight. But the first love was certainly the most entertaining of all Walpole's writings: his letters, addressed to various friends, collected by himself, and published at different times since his death, Walpole Scott calls him the best letter-writer in the English language, and Byron speaks of his epistolary talents as "reserved and unassuming, and must be placed upon them as an historical work, for the author's prejudices and political partialities are too open to entitle his evidence or judgment to much weight. have been the work of a man of the highest talent; but a less exalted opinion is necessarily formed of the man, when we discover that the ease and freedom of style which he has so successively entrapped into admiring as natural, were the result of laborious care and study. He has always in mind the art of selecting anecdotes, and dressing up epigrams which he afterwards inserted in his letters as if they had occurred to him at the moment. Many of his letters were published in the first edition of his works in 1798, and subsequently his letters to Mr. Macpherson, to the Rev. Lord Hertford and the Rev. Henry Zouch, and lastly to Sir Horace Mann, have appeared in different times. The last are the most valuable and complete collection for reasons of fact, by their accuracy, and Lord Whittworth's preface to that correspondence. ‘Sir Horace’s constant absence from home, and the distance of his residence (at the court of Tuscany) from the British islands, made every occurrence that happened acceptable to him as news. In consequence, his correspondent relies on him everything that takes place, both in the court and in society, whether the anecdotes are of a public or private nature, and hence the collection of letters to him becomes a most exact chronicle of the events of the day, and elucidates very amusingly, both the manners of the time and the characters of the persons then alive.’ The whole of the letters of Horace Walpole have since been collected, and were published, in 1840, in six volumes, octavo. This series comprises a period of more than sixty years, from 1735 to 1797.

Horace Walpole had not been contented with collecting rare and curious books and publishing his own works, but, still further to gratify his literary tastes, he established in 1757 printed the Odes of Gray with Bentley’s illustrations; his own ‘Anecdotes of Painting; a Description of Strawberry Hill; a quarto edition of ‘Lucan,’ with the notes of Godwin and Bentely; a ‘Life of Lord Herbert of Cherbury,’ by himself; Hentzner’s ‘Art of Painting,’ and Lord Whittworth’s ‘Account of Russia.’ He had also, so early as the year 1768, formed an intention of printing a quarto edition of his own works, which he soon afterwards commenced. But he had time to complete only the second volume, in consequence (as his editor, in 1798, says) of the order in which he had used the title when he could avoid it. Some of his letters after that period were signed by ‘the uncle of the late Earl of Orford.’ He lived for six years afterwards, in the full possession of all his faculties, though his limbs had been long attacked by gout, which, however, did not prevent his being able to carry on his literary labours. He died in the 80th year of his age, at his house in Berkeley Square, on the 2nd of March, 1797.

Horace Walpole cannot be regarded either as a wise or as a great man. Weakness, vanity, and inconsistency were prominent features of his mind, and his works do not prove it to have been susceptible of great elevation of thought or principle. He had a natural taste for small and trifling art, and he was particularly fond of the business of life; but then it is true that he always professed to be a gentleman of ease and fashion, whose literary efforts were undertaken not for fame, but for recreation. He affected to disclaim the character of a man of letters, and he was acutely sensitive to criticism, greedy of praise, and envious of the fame of others. He pretended to despise the court, yet all his thoughts were of kings, princes, and courtiers. He was a republican and an aristocrat. His own theory of literature was that a novel was a gentleman’s essay, a man of letters is a gentleman of arms. He was not content to assume it. In private life he showed no remarkable virtues, nor is he chargeable with any serious faults.

The living of Walsingham is a vicarage, of the clear yearly value of 363l., with a glebe-house; the perpetual curacies of St. Paul and Bloxwich are of the clear yearly value of 50l. and 142l. respectively; Bloxwich has a glebe-house. The value of Walsingham Wood is not given. All are in the

rural deanery of Tamworth and Tutbury, the archdeaconry of Stafford, and the diocese of Lichfield and Coventry.

There were in the parish, in 1833, one infant-school with 35 boys and 36 girls; twenty-one other day-schools, with 702 boys and 712 girls; making a total of 1293 children or about one in twelve of the population under daily instruction. One of the day-schools was an endowed grammar-school with 60 boys; another an endowed English school with 54 boys; two were national and blue-coat schools, with 194 boys; and the others were partly supported by endowment or subscription, and one by a grant from the grammar-school. Four
day-schools were also Sunday-schools, with 298 boys and 242 girls; besides, four of these were other schools for children, with 670 boys and 526 girls; making a total of 1738 children under instruction on Sunday. There are some almshouses and several charitable bequests for the poor of the town. Races are held about Michaelmas, and assizes at the constabulary. (Rickman's

WALSAM, NORTH. [Norfolk.]

WALSAM, NEW AND OLD. [Norfolk.]

WALSAMING, or WALSAMINGHAM, THOMAS, an English coal-miner, and the key period in the life of the fifteenth century, was a marriage of convenient interest. Bishop Nicolson conceives that he was 'very likely a proximus juris professor of history in that monastery about the year 1440.' He is the author of two historical works, one written in French, the other, 'Hystoria Brevis,' ab Edwardo primo ad Henricum quintum' ('it extends in fact a.d. 1273, the first year of Edward I., to 1422, the last year of Henry V.); the other, 'ypodium Neustriae, ab ibi annum 6 regni Henrici quinti' ('A.D. 1418). Both these works were published together by Archbishop Parker, in folio, at London, in 1574. Both are also contained in Camden's 'Anglica, Normannica, Hibernica, Cambriae a Varibus Scoticis, Normannis, et Frans, et Libris de Historia Brevis,' from p. 57 to 408; the 'ypodium Neustriae, from p. 409 to 592. Walsingham, in his 'Hystoria Brevis,' takes up the narrative from the point where Matthew Paris ends; and he might well, Nicolson observes, 'seem to be Parties at the Constanta,' his language answerable to his matter.' But although his style is not to be commended, Walsingham has in both his works preserved many facts which are not elsewhere to be found. His account of the reign of Edward II., according to Nicolson, is wholly based on Sir Thomas de la More Moor, a contemporary writer, who drew up a Life of Edward II. in French, of which there is also a Latin translation in Camden's 'Anglica,' Sec., pp. 593-693.

Or WALSAMINGHAM, SIR FRANCIS, an English statesman of distinguished ability, was descended from an ancient family, and was born at Chiselhurst, in Kent, where he is commonly stated in the year 1536. The authority for this date we believe to be an account, transmitted by a correspondent to the publishers of a work called 'British Biography,' vol. iii., svo., London, 1767, of an original picture of Walsingham painted in 1578, making him then forty-two years of age. (See note to p. 286.) He was the third and youngest son of William Walsham, Esq., of Sevington, in the county of Kent, and Ann, daughter of John of Joice, daughter of Edmund Denny, Esq., of Cheshunt in Hertfordshire.

After studying at King's College, Cambridge, Walsingham went to travel on the Continent; and he remained abroad, making active use of his knowledge of the state of foreign countries and acquiring their languages, till after the accession of Elizabeth. On his return to England his accomplishments recommended him to the notice of the profession under whose hands he was soon introduced to high and confidential employment in the public service. His first important mission is generally assumed to have been to France in the earlier part of the reign of Charles IX., but nothing further is known of it than what is stated in the letter of recommendation (mature jam estate) he was Queen Elizabeth's orator, or representative, at the court of the king of France (apud

Galium), for several years, in a most turbulent time. But it does not appear why the words in the epigraph may not refer to what is generally called Walsingham's second French embassy, upon which we know that he was sent in August, 1572, and returned, with all his attendants, in 1573. On his return home he was appointed one of the principal secretaries of state and sworn of the Privy Council; and soon after he was knighted. In 1578 he was sent as ambassador to the Netherlands; in 1581 again to France; and in 1582 to Scotland. In October, 1583, he appears to have still occupied himself chiefly with the conduct of foreign affairs, and it must have been in that year that, if we are to believe a story which is commonly told, he retired to his castle, the preparations of which were made by the Spanish Armada, by getting the bills upon which the money was to be raised protested at Genoa, through the agency of Sutton, the founder of the Charter House, having previously discovered the design of the King of Spain in pressing upon Eber armament by having the effect of his majesty to the pope, in which the secret was intended, stolen from the cabinet in which it was looked up, though the medium of a Venetian priest retained as his spy at Rome, who got a gentleman of the bedchamber to take the key out of his hand, and was put to death. Such a proceeding, strange as it now sounds, was not at all foreign to the spirit or practice of the statesmanship of that age, and was quite after the manner of Walsingham, whose whole system was founded upon and maintained by money. There can be no doubt that, in reference to his policy, he was an excellent man. He had a great respect to the extension of popery by any means whatever, and thought that, in the end, it was the only way of recovering the English crown. He believed the monarchy to be united, and the crown to be the key of all power and authority. He would not have any heretics in the land, and believed that, if there were but a few, it would be a great joy to him, says his warm admirer and panegyrist, Lloyd, 'men's faces spake as much as their tongues, and their countenances were index of their hearts. He would so beat the nation that no one was left to have the name of Norman. He discovered whether they answered or were silent. He outdid the Jesuits in their own bow, and overreached them in their own equivocation and mental reservation; never settling a lie, but warily drawing out and discovering truths. He was a thorough man, a medium between the minister of the popish church and that of the Protestant church, and a favor to most of the papists before their death, as they had been to their brethren before their treason. He maintained fifty-three agents and eighteen spies in foreign courts; and, for two pistols an order, had all the private papers on. He could write his contents without touching the seals.'

For all this, Walsingham was the very reverse of a man of mere policy and expediency. His principles were so fixed and distinct, that his morality was strict, to the verge of asceticism; his religious zeal drew him all his life towards puritanism, and in his latter days he led his life like a monastic, and in his last days it was with a devotional spirit that he retired from business, and to have spent his time, with little or no society, at his house at Barn Elms. Here he died on the 6th of April, 1590. He was,' says Camden, 'one of the most steady asserter of the reformed religion, endured well the intrigues of government and as well as they could, and improved the good affections of the people, so as to serve his own turn; insomuch that his quickness and dispatch of business made him be considered by the queen as a man that ever outdid himself; and the papists, against whom he had so many enemies, and among these, that intelligence and penetration, and so dexterous at finding out their tricks and designs against religion, his prince, and country, that they complained of him as a very useful and insidious man. Indeed, he watched the practice of those favours, and connived at his estate by that means, and brought himself so far in debt, that he was buried privately by night, in St. Paul's Church, without any manner of funeral solemnity, 'Elizabeth, who had a high opinion of his sagacity in public and important services, seems to have kept him throughout his life on short allowance. Even of honours, if we except his knighthood and the offices to which he was appointed, he had none. Camden says he was a Knight of the Garter, and has only alluded to the matter, it was supposed, because it was an unsual one. We believe it is unfounded.

Walsingham was married to a lady of the name of St.
Barbe, and by her he left one daughter, Frances, who became successively the wife of Sir Philip Sydney, of Robert Devereux, the unfortunate Earl of Essex, and of the distinguished soldier Richard Burch, created by Charles II. Earl of St. Albans in the English peerage, but better known by his inherited Irish title of Earl of Clanmellie. She died, after bringing her last husband a son, in 1602.

The history of Walsingham’s French embassy of 1670–1673 is contained in Sir Dudley Digges’s ‘Complete Amb-}

mation’ of the intended marriage of the Queen Elizabeth, of glorious memory; or, comprised in letters of negotiation of Sir Francis Walsingham, her resident in France; together with the answers of the Lord Burleigh, &c., folio, Lon., 1635. There is a short paper by Wal-}

singham to his ‘Monomachia’ (c. 1556), saying that directed against Walther were unfounded, though it appeared that the Wittenberg edition was sometimes incorrect, a reproach however to which the Jena edition was likewise liable. Another polemical pamphlet of Walther was, 1, ‘Antwort auf die Flacianische Lügen und Bilche. Berlin, Wittenbergische Tomia der Bücher des ehrwürdigen Martin Luthers, wider Matthes Flacian Ilyrium,’ Wittenberg, 4to., 1656. Mayerus, in his work ‘De Versione Bib-}

liothecis Catholicarum’ (c. 1583), says that the edition cited, directed against Walther, was not the later ones, but the one from 1550. Also, 2, ‘Bericht vom Unterricht der Biblen und anderer Bücher Luthers,’ 3, ‘Register aller Bücher und andere Schriften Wittenbergs in deutscher Sprache.’

WALCHER, JOHANN GOTTLIEB, a celebrated anatomist, was born at Königsberg in 1739; the ‘Biographie Universelle’ says of the year 1800 specimens, the result of the dissection of upwards of 8000 dead bodies. He wrote several works on various departments of anatomy and midwifery. In addition to numerous essays and papers, he published the following works:—‘A Treatise on the Bones of the Human Body’ (translated into Latin by Dr. Rothen Knochen), Berlin, 1762, 8vo.; ‘Observationes Anato-

micae,’ Berlin, 1775, fol.: ‘A Manual of Myology’ (‘Myologisches Handbuch’), Berlin, 1777, 8vo.; ‘On Diseases of the Abdomen and on the Anatomy of the Bones of the Sphinters and of the Schlaglgress,’ Berlin, 1785, 8vo. Of these the anatomical works have gone through several editions, and his miscellaneous papers are valuable contributions to medical science.

‘Bibliographie Universelle: Neueste Conversations-Lexicon; in both of which a list of his numerous works and papers is given.’

WALTHAM ABBEY. [Essex.]

WALTHAM, BISHOPS. [Bishop’s Waltham.]

WALTHAMSTOW. [Essex.]

WALTHER, CHRISTIAN, was probably born in Hesse, in the beginning of the sixteenth-century. He studied divinity, took orders, and lived a considerable time in a convent of monks, in which he was much injured. He afterwards left his convent and adopted the Protestant religion. Having settled at Wittenberg, he became acquainted with several of the great Protestant divines of the sixteenth century, and was4

recommended by them to his present instructor (Professor Barenbruch), and Asmuth, who esteemed him for his extensive learning. He also became acquainted with the celebrated printer Hans Lufft, in whose office he was employed as corrector of the press for thirty-four years. He was the author of several books of divinity, among which the most remarkable are ‘Protestantische Lieder’ (1785), which edition was attacked by the divines assembled at Jena for the purpose of publishing another edition; they charged Walther with having purposely altered several passages so as to make them an instrument in the hands of the Calvinists for their attacks against Luther. The celebrated Asmuth (the bishop) attacked Walther in a pamphlet entitled ‘Das die zu Wittenberg und andern Theilen der Eucharistia im Buache, dass die Worte, das ist mein Leib, noch stet sithe, mehr denn ein Blut und 4 gantz Paragraphes vorlettzlich ausgewlassen haben.’ He was likewise attacked by Flacius. Walther went out of the man to prove such passages in silence; he defended himself in a pamphlet, ‘Bericht vom Untersuchung.’

WALTHER, or GUALTERUS, RUDOLPH, was born at Zürich in 1519. After having studied Protestant divinity in several schools in Switzerland, he went to Marburg in Hesse, and made himself known as a learned divine and an able negotiator in those politico-theological transactions which, according to the circumstances, either embittered or quieted Germany. He accompanied the landgrave, Philip the Magnanimous, of Hesse to the diet of Regensburg in 1541, and, although he was rather young, the landgrave put him at the head of the Hessian divines who were present at the diet. At Regensburg, Walther made the acquaintance of Melanchthon, Bucer, Sturm, and other eminent theologians. He returned to Switzerland in the same year, 1541, and was appointed head master of the Schola Carolina at Zürich.

The principal works of Walther are: 1, ‘Apologia Zwinglii.’

Walther became soon an adherent of Zwingli, and more than once attacked Luther. 2, ‘Monosxochia Davidis de Goliath’ (1541), a poem written by Erasmus and translated into Latin by Walther, ‘Epitomatum Novum Testamentum,’ published by Josias Simler, the divine, Zürich, 1594, fol. He has also written, 4, ‘Homiliae in Joannis Epistolas; in 12 Prophetae Minores; in Christum in Mabathum; in Lucam; in Acts Apostolorum; in Epistolam ad Romanos; in Epistolam ad Corinthisios; in Epistolam ad Galatas;’ and a great number more. 5, ‘Argumenta omnium tam Veteris quam Novi Testamenti Capitum’; the author has made these arguments the subject of an elegiac poem, written in Latin verse. 6, ‘Nabales, Comedica Sacra ex Samuele, I. c. 25;’ and several other Latin poems, among which there is one on the learning of the German nobility. 7, ‘Apologia ad Catholicae Ecclesiae pro Ulrico Zvinglii, episcopi Dubendorfensis,’ 8, ‘Testae toctae, cum Argumenta, Dispositionibus, et Explicationibus;’ 9, ‘Ulrici Zwinglii Libri XXIV;’ this is a Latin translation of Zwingli’s sermons and other writings.

Wanhauptig Bekümmernissen der Kirche und ihrer Verteler, der bisher gegebührnder Antwort auf Lutheri Verdamnnisse und Schelten,’ in German and Latin. Walther’s name is mentioned among the most eminent German divines of the sixteenth century. Some say that the Latin of the ‘Verdamnnisse’ and of the ‘Psalter’ (translated by Valtebius, who was also the author of the ‘Guteleb’, who died in Paris in 1547, and who translated some books of Aristotle) is made by Walther.

(Verheiden, Prostamentum aliquot Theologorum qui Romanum Antichristum crestitse opponuntur, Elygiae, Logica, Opera; p. 251, &c.; Jochen, Allgemeines Ge-}

WALther, Michael, born in 1593, was the son of John Walther, a rich merchant and patrician at Nuremberg, who intended to bring his son up to his business, for which purpose he sent him to a rich merchant at Thas in Bohemia. Young Walther however disliked trade, and his father had him educated for a scholar. In 1610 Walther went to the university of Wittenberg, where he first studied medicine, but he afterwards pursued theological studies at Giessen, Altdorf, and Jena. In 1618, Elizabeth, duchess of Saxony, settled him at Jena, and in 1621 her son, Duke Julius Frederic, gave him a chair of divinity in the university of Halle. In 1626, Rudolph Christian, sovereign count of Oestriechland, conferred the dignity of divinity to the superintendent of the Lutheran church in his dominions. Several distinguished works on divinity which he published during the course of these years had made his name known in Germany, and the universities of Rostock and Wittenberg both offered him a chair of divinity, which however he declined.

However, in 1642 he accepted an invitation of Frederic, Duke of Brunswick-Luneberg, who appointed him general superintendent of the Lutheran church in his duchy. He died at Zelle, on the 8th of February, 1652. His principal works are: 1. ‘Harmonia et Logica Salomonis,’ 2. ‘Of. Clara Bicha,’ Nuremberg, 1636, 4to.; 3. ‘Theoriae et Practicae illuminatae,’ 4to.; 4. ‘Tractatus de Manna, Leiden, 1633, 12mo.;’ 5. ‘Exercitationes Bibliicae,’ Nuremberg, 1638, 4to.; 6. ‘Quadragesimae Miscellaneum Theologicum, this book was the forerunner of—7. ‘Centuria Miscellaneum Theologicum, 8. Giessen, 1646, 4to. In which the author discusses one hundred difficult questions concerning divinity. Similar works are: 8. ‘Liber singularis Quaestorum et Responsorum Theologicum, per epistolas;’ 9. ‘Spiegell Controversiarum illustrissimorum, per XXII. de Dei Nominibus;’ 10. ‘Postilla Mosicae, oder Erklärung etlicher Historien, Fürbilder, und Sprüche aus den fünf Büchern Moses;’ 11. ‘Postilla Evangelica;’ 13. ‘Der Gudelse Schlüssel des Alten, und der samt Kern des Neuen Testaments, der richtliche Erklärung der Sechzehn. Epistel S. Pauli an die Hebräer;’ this book was much esteemed. The learning of Walther was unanimously acknowledged, but the length of his works and his want of taste in the arrangement of his materials were condemned. Walther had a son, called Michael Walthers, like his father, who was born at Aurich in 1638, and who became professor of mathematics, and afterwards, of divinity, in the university of Wittenberg, where he died in 1692. He published works in various fields of mathematics and divinity. The principal are: 1. ‘Disquisitio Mathematica de mutuis Siderum Radiamionibus quas vulgo Aspectus vocant, Wittenberg, 1660, 4to.;’ 2. ‘De Harmonia Musicae,’ 3. ‘De Legissima Operis contra Socinians et Armignians;’ several dissertations on cones, the golden number, the torrid zone, on geographical longitude, 

Walther, Georg Christoph, a German and a consul, was born in 1601, at Rothenburg, formerly a imperial town on the Tauber in Franconia, and 1618 he went to Sondershausen, where he took his degree in law in the university of Altdorf. In 1631 the senate of his native town appointed him president of the chancellery of justice, which office he held till his death, in 1686, in 1645 he was made professor of public law of Germany, several princes and other members of the circle of France who employed him as their representative during the different diplomatic transactions which either preceded or followed the peace of Westphalia, in 1646. Walther was a member of the Academy of St. Statu, Juribus et Privilegia Doctorum; 3. ‘De Meta et Hostipationibus Militaribus;’ 4. ‘De Remuneratione Successionum vel Haereditatis;’ 5. ‘Harmoniae Theologiae-Juridico-Politico-Philosophica,’ which was published after his death.

Walther, Christian, a German divine ofconsiderable merit, was born in 1653, at Nottwig, not far from Königsberg, where he began his academic studies, which he continued at Leipsig, and finished at Jena. He took his degree of M.A. at Jena, in 1677, and returned to his native country, where he held several ecclesiastical offices. In 1705 he was appointed professor of divinity in the university of Jena. In 1746 he was invested with the office of inspector of the synagogu of the Jews in that town. During some time he was rector of the magnificent university of the kingdom of Königsberg, where he died in 1717. His principal works are: 1. ‘Tractatus de Cultu Divino sanctiuretis Vercenenti, quem stano sub episcopatbat;’ 2. ‘De Duabus Tabulis Lapidatis;’ 3. ‘De Quatuor Foenarum generis subd Hebraeos;’ 4. ‘Dispinitions VIII. de Plurilitate personarum in Divina, ex Genesis;’ 10. ‘Dispinitions III. de ingresso Sacerdote colonae Foenarum dion In knitting t ignorch saecularis, Emendatio, Salomonis, Inscrip. Programmat A. V. de Semine Abrahæ in qua benevolent Omnes Gentes.’ Walther also published the beginning of the work of Moses Maimonides on Circumcision, with notes and a Latin translation.

(Jecher, Allgemeines Gelehrten-Lexicon.)

Walther, Heinrich Andreas, born in 1606 at Königsberg in Hesse, became minister at Woms in 1729, and in 1733 he was appointed minister at St. Catherine’s, in the town of seventeenth century. He was a member of the Protestant clergy at Frankfort was conferred upon him, and in the same year the faculty of Giessen created him doctor of theology. He died at Frankfort in 1743. His principal works are: 1. ‘Disputatio ex Anti-Quaesturis, Ordinis;’ 2. ‘De Harmonia et Logica Salomonis, Emendatio, Giessen, in 1729; 3. ‘Programmat A. V. de Semine Abrahæ in qua benevolent Omnes Gentes.’ This book has been imitated by several later writers, and has given birth to an excellent work for the use of children, entitled ‘Lehren der Weisheit und Glaubens durch die bibelweisen Kinder, and accompanied with a preface the Frankfurter Catholichs.’

Walther, Christoph Theodousios, was born at Schildberg, in Brandenburg, in 1659, and studied divinity at Hall, 1722, and Frederic IV, king of Denmark, applying to the faculty of Halle for the purpose of obtaining some young theologians who would go as missionaries to the Danish possessions in East India, Walther accepted the invitation, and arrived at Ceylon, 1725, accompanied by Henry Plittschow and the celebrated Bartholomew Ziegenbalg. They arrived at Tranquebar on the 9th of July, 1706, and until then the Danes had not succeeded in propagating Christianity beyond those limits of their possessions, The Walther, accompanied by Portuguese, with Tamul and several other Indian dialects, visited the whole coast of Coromandel, and his pious zeal was rewarded with great success. He founded the missionary establisment.
WALTON, A genius of plants belonging to the natural order Sterculiaceae, the name of which is intended to commemorate three individuals who have contributed to the advance of botanical science: A. F. Walther, formerly professor of medicine in the University of Leipzig, who published, in 1720, a work containing descriptions of trees and shrubs. Walton, an English botanist and author of the "Flora Caroliniana," published in 1738; and Richard Walton, who accompanied Lord Anson in his voyage round the world in 1740-1744.

The genus is known by possessing a 5-angled calyx, furnished with a lateral 1-3-lobed deciduous involucre; 5 petals; a single style with tuberculated or pencilled stigma; a 1-celled, 2-valved, 1-seeded capsule. The species is a small tree or shrub. The flowers are yellow, the flower heads in axillary or terminal stalked heads, rarely in panicles, rising in clusters from the branches.

W. Americana has ovate-oblong leaves, plaited, serrated, and tomentose; the heads of the flowers axillary; the calyx, petals, and capsules of the same color. This plant is a shrub about 4 feet in height, with yellow flowers. It is a native of the Bahamas Islands, of Surinam, and the Caribbean Islands.

W. Durandina has a suffrutescent ascending stem, with oval or ovate-oblong leaves, obtuse, and entire at the base; the lower ones pilose, the upper ones tomentose and glaucous; the heads of the flowers terminal and axillary; the calyx pubescent; the petals bearded above the claw; the tube of the stamens entire. This plant is a native of Brazil and Argentina. The species is called Durandina or Durandina. This plant, like the whole of the order to which it belongs, contains much mucilaginous matter, and is used in decoction in the Brazils, as a remedy for phthisis, the chest, and also in some of the forms of venereal disease. It is also used as an external application to wounds.

There are several other species of Waltheria: they are most of them inhabitants of South America, and are generally inconspicuous shrubs. They are of easy cultivation, and will thrive in a loamy soil or a mixture of loam and peat, and may be readily propagated by cuttings.

WALTON, BRYAN. [Polyglots.]

WALTON, Izaak, the "Father of Angling," was born at Old Hall, near Battle, Sussex, on the 5th August, 1593. The register of baptisms and burials supplies the name of his father, one Jervis Walton, who appears to have been of the rank of a gentleman. Nothing more is known of this person, except that he died in the year 1560-7, leaving his son Izaak, it is supposed, an orphan.

From the time of Walton's birth up to the age of twenty, nothing is known of him. It is presumed that he was apprenticed to a relation of the same name who dwelt in London, and was called Mr. Walton, or Mr. de Walton, but the identity of trades seems to be the sole ground for this conjecture. He must however soon after the age of twenty have been engaged in business on his own account, for, in 1624 Sir John Hawkins, in his possession of the "Adventurers," writes, "Walton dwelt on the north side of Fleet Street, in a house two doors west of Chancery Lane, and abutting on a message known by the sign of the "Harrow," and that his house was then in the joint occupation of himself and a hosiery called John Mason." About 1623 (a year before the date of this deed) Walton states that he first began "a happy affinity" with the family of his first wife, Rachel Froud, a descendant of Archbishop Cranmer. He was married to this lady on the 27th of December, 1626.

It was doubtless owing to this marriage that Walton first became interested in Hooker, the author of the "Laws of Ecclesiastical Polity." George Cranmer, his wife's uncle, having been Hooker's personal friend, communicated the materials for the admirable Life of Hooker which Walton wrote during his residence with Dr. Morley in 1633: it was not however published until 1645.

Sir John Froud's son, John, afterwards Dean of Rochester, was the most interested person in the publication of this work, and it was printed at the end of Donne's poems published by his son in 1633. This elegy seems to be Walton's first avowed literary effort, and in it he speaks of Donne's "powerful teaching" and calls himself "to convert," which gives a clue to the intimacy between Walton and Donne. Sir Henry Wotton requested Walton to collect materials for a Life of Donne, of which Sir Henry himself had thought of writing, but his death in 1639 put an end to the design. Walton believed that these materials were to be published without a preface, determined on writing it himself, and in the introduction to the Life, published with the Sermons in 1640, he fully explains the reasons which induced him to become Donne's biographer.

Previous to this publication Walton had removed into Chancery Lane, a few doors from Fleet Street, where his wife gave birth to two sons, both of whom however died. After this calamity, in August, 1640, very much depressed, Walton retired to the wilds of America, and in 1644 he returned to London, as is known from the entry in the register of St. Andrew, Holborn, where his son, Richard, was born in 1641. In this same year Walton published a collection of Sir Henry Wotton's letters, poems, &c., under the title of "Reliquiae Wottonianae," to which he prefixed the Life of Wotton.

Walton had by his marriage connections identified himself with the Royalist party, and the strongly expressed approval of Charles I. of the "Life of Donne," combined with other circumstances, rendered him very zealous in a good cause, and during the first part of his life, the "Lesser George" having been confirmed to his care after the battle of Worcester, by Charles II., for safe conveyance to London. Ashmole details this service in his "History of the Order of the Garter," and declares that Walton was "well known, and as well beloved of all good men."

In 1653 the work upon which his fame principally rests appeared—"The Complete Angler," or "Contemplative Muses Recreation," a work which to us, Lords of Sir Harry Nicolas, whether considered as a treatise on the art of angling, or as a beautiful pastoral, abounding in exquisite descriptions of rural scenery, in sentiments of the purest morality, and in the unaffected love of the Creator and his works, has long been ranked among the most popular compositions in our language."

In 1654 the second edition of the "Reliquiae" and in 1655 the second of the "Angler" appeared. Between this period and 1659, the date of the appearance of the latter, one of Sir Nicholas Barbon's "Lamps," a work which to us, Lords of the Admiralty, was an interesting volume, was written. In 1659-60 Donne's Life was first published as a separate work. At the Restoration, two years afterwards, Walton testified his joy by addressing an "Humble Eclogue" on the subject to Alexander Brome, printed with that writer's poems, and published in 1665.

During the troubled times preceding the Restoration, Walton had become intimate with Drs. Morley and Saxonden, who were now elevated to the unexpected seats of Worcester and Lincoln. Another friend of Walton's, ...
King, was also reinstated in the see of Chichester. In 1662, having again become a widower, he left his residence, which had been in Pater-noster-row, and went to live with Dr. Morley, who was just then made Bishop of Winchester. At this time also he took the lease of a house in Paternoster-row, called the Cross Keys, which was burned down in the great fire.

In 1670 the Life of George Herbert was published, a prebendary of Winchester Cathedral. Walton's son is supposed to have been educated by his maternal uncle, Thomas Ken, also a prebendary of the same cathedral, for in 1676 we find him graduating together on the Continent forming a regular part of the education of those days. Young Walton was soon after admitted at Christ Church, Oxford.

In 1676 Charles Cotton, Walton's well-known condictor in the later editions of the 'Complete Angler' (Cotton contributing a treatise on fly-fishing to that work), and a poet of some merit, as his 'Remains' testifies, comes into notice. He built the fishing-house on the banks of the Dove, near his own house, Beresford Hall, and there was his old age found the ease and retirement which he so well deserved. In the year 1678 his last literary efforts appeared; the Life of his friend Bishop Sanderson, and an introduction to a poem by John Caius, 'Daniel's Vision.' The misfortunes of Archbishop Laud, concerning which strange mistakes have been made. Many persons attributed it to Walton himself, but Sir Harris Nicolas has proved that the family of Walton's second wife intermarried with a family of this name, and through them the poet got access to the Archbishop's papers. An anonymous tract, printed in 1680, entitled 'Love and Truth,' is attributed to Walton, but upon slender authority.

Walton died at the house of his son-in-law, during a severe storm on the 13th of December, 1683, and lies buried in Winchester Cathedral.

Walton's son became a canon of Salisbury Cathedral, and is said to have contributed largely to Walton's 'Sufferings of the Clergy,' and to have most hospitably received Bishop Ken when deprived of his bishopric. He died in 1720, and Anne Walton in 1715. There are no descendants of the name of Walton living. A good portrait of 'Old Isaak,' by Houseman, was bequeathed by a descendant to the National Gallery.

There are the existing editions of the 'Complete Angler,' from that of 1653 to that of 1833. This last is a splendid work in two quarto volumes, edited by Sir H. Nicolas, who has written the first good Life of Walton. There was also an edition of all Walton's works by Major, in 1823. Dr. Zumbusch's poor Life of Walton, prefixed to an edition of his 'Lives.'

WALTON-ON-TAMES. [SURREY.]
WALTZ (from Waltzen, Germ. to roll), a gay dance, in triple time, and executed by two persons, who, almost embracing, rapidly turn round on an axis of their own, while moving quickly in a circle whose radius is from ten to twelve feet, according to the dimensions of the room.

Dr. Burney with much naïveté says, 'Having seen the Waltz performed by a select party of foreigners, we could not help reflecting how uneasily an English mother would be to see her daughter so familiarly treated; and still more to witness the obliging manner in which the French would be to the English.' It is observed that the tune used to add that the remark was made before the waltz had been introduced into the British Isles.

WALWORTH, WILLIAM. [MACCABE.] WANDSWORTH. [SURREY.]
WANGA/RÁ is a country in Northern Africa, unknown to the ancients and also to modern travellers, but mentioned by the Arabian geographers Edrisi, Abulfeda, and Ismail. These authors agree in stating that in Wangara the Niger terminates, and Leo Africanus adds that it terminates in the sea. According to our present knowledge we must suppose that Wangara is the delta of the Quorra, and this supposition is supported by the description which is given of the country. The authors above mentioned describe it as an alluvial tract and intersected by the branches of the Niger, and annually overflowed by the rains of July, and in which there are several fresh-water lakes are found in it. Leo Africanus says that the low tract is called Genni by the inhabitants, and that it is contiguous to Wangara, which thus would extend from the mountainous region of the Quorra and the Thadda. The name of Genni or Guni appears even at present to be used in Northern Africa for the delta of the Quorra, and this name seems to be derived from that of Guinea, which Europeans have been able to apply to that portion of the Continent forming a regular part of the education of those days.
New Testament (published in 1597). After this he was taken into the service of Dr. Chariot, master of University College, who kept him at his own lodgings, and seems to have employed him in transcribing, compiling, abridging, and other such work. Chariot also got him appointed one of the under-keepers of the Bodleian Library; and he took a principal part in drawing up the Indexes to the Catalogue of MSS., the Latin preface to which is of his composition. He then left Oxford, and removing to London, became secretary to the Society for Promoting Jocher's historical works, and his employment was as assistant to Dr. Hickes, the eminent Anglo-Saxon scholar, for whom he travelled over the kingdom in search of manuscripts in that language, and drew up in English a catalogue of those contained in the public and private libraries and other repositories visited by him, which, after it had been translated into Latin by another hand, was printed in Hickes's 'Theaurus Linguarum Veterum Septentrionalium,' 31mo., fol. Oxon., 1725, and forms the third volume of that great work. This is Wanley's principal performance; and it is admitted to be done, all circumstances considered, with diligence, care, and competent learning. His last employment was as librarian to Harley, Earl of Oxford, the founder of the Harley library, and he compiled lists of manuscripts, and to his son, the second Earl, both of whom were highly satisfied with his services in that capacity. He compiled the Catalogue of the MSS., which was first printed in 1702, as far as to No. 2407. Among the London libraries which were visited by him is the famous London Diary, kept by Wanley, from March, 1715, till within a fortnight of his death, mostly of proceedings connected with the Harleian library. Several extracts from it are printed in the 'Anecdotes of the English translators of the Old Testament,' by Leonard Epper, published at London in 1778. 'The only separate work published by Wanley is a translation (from the French) of Ostervald's 'Grounds and Principles of the Christian Religion,' which appeared at London in an 8vo. volume, in 1704.

There are many letters relating to Wanley, principally from his contemporary and fellow antiquary Hearne, in the 'Letters of eminent Persons of the Seventeenth and Eighteenth Centuries, from MSS. in the Bodleian,' published at Oxford in 2 vols., in 1813. And there are several of Wanley's own letters in the volume lately printed for the Camden Society, entitled 'Original Letters of eminent Literary Men of the Sixteenth, Seventeenth, and Eighteenth Centuries.' There are also letters from him to Sir Henry Ellis, K.H., F.R.S., &c., 4to., 1843.

WANSIDI. [Somersetshire.]

WANSELEBEN, JOHANN MICHAEL, son of a Lutheran clergyman, was born at Erfurt in 1635. After the study of divinity and theology at Königsberg, he was successively private tutor, soldier, and vagabond; at last he attached himself, for the purpose of studying the Ethiopic, to Ludolf, at whose request he undertook a journey to London. The object of his excursion was to superintend the printing of Ludolf's ''Lexicon Ethiopicum'', which was published at London in 1661. Wanseleben was also employed, during his residence in England, by Edmund Castell, as an assistant in compiling his 'Lexicon Heptaglotrum.'

Wanseleben, on his return to Erfurt, was sent by Duke Ernst of Gotha, at Ludolf's suggestion, to examine into the condition of the Christians in Egypt and Abyssinia. He performed the Egyptian part of the undertaking, but returned to Europe without attempting to penetrate into Abyssinia.

He landed at Leith, in February, 1665, and proceeded to Rome, where he declared himself a convert to the Romish church, and soon after entered the Franciscan order. In 1670 he visited Paris, and was sent to Egypt by Colbert, for the purpose of collecting information respecting the state of the country and purchasing manuscripts. He landed at Damietta in March, 1671, and left Cairo for Constantinople in September. He, however, remained in Constantinople for some months, and was able to visit the convent of the Delta, the Faiyum, the deserts of St. Macarius and St. Antony, in search of manuscripts, and ascended the Nile as far as Esneh. He made several excursions from Constantinople into Asia Minor, and was preparing to return to Egypt when he was recalled to France.

He reached Paris in April, 1676; but instead of obtaining the objects of his ambition, a bishopric or professorship of Oriental languages, he was called to account for the money entrusted to his disposal, and disgraced for misappropriating the same. Upon being discharged by a grant of public money, he managed to print the Ethiopic works he had collected, his narrative of his journey, and a catalogue of the manuscripts in the library of the Château of Fontainebleau, where he died, on the 18th of June, 1679.

Ludolf, in the preface to his commentary on the 'History of Ethiopia,' speaks respectfully of Wanseleben, but his opinion may have been biased by the connection of the former scholar; he must have entertained some respect for Wanseleben's requirements when he sent him to London to carry his Ethiopic Grammar and Lexicon through the press. The published works of Wanseleben are: — 1. Index Latinus in Jobi Ludolfi Lexicon ''Ethiopicio-Latinum'; Appendix ''Ethiopicio-Latina, Liturgia S. Diocesarii, Patriarchae Alexandrini, ''Athiopi et Lat.'', Londini, 1661, 4to. 2. ''Conceptus Operum ''Ethiopicorum quae ad extendendum Principes Catholici'' et ''Libri ''Ethiopicorum'' decrevunt'' et ''Septemiarium vero'' (published by Paris in 1671, Parma, 1672), 8vo. 3. 'Nouvelle Relation, en forme de Journal, d'un Voyage fait en Egypte en 1672 et en 1673.' He was also a member of the Royal Society. This edition contains much more in detail than the Italian version: a 'History of the French establishment in Egypt,' published at London in 1678; 5. 'Histoire de l'Eglise d'Alexandrie fondée par St. Marc, que nous appelons celle des Jacobites Copistes d'Egypte, écrite au Caire même en 1672 et 1673, et traduite en France en 1675, 12mo.' 6. 'Voyage de Wansleben, une learned Papist, may have been compiled from his narrative. A MS. entitled 'Diarium conscriptum a J. M. Wanslebio, Societate Thuringiana,' ab anno 1674, is said to be preserved in the Duela library at Weimar.

WANSTEAD. [Essex.]

WANTAGE, a market-town in the hundred of Wantage, in Berkshire, 63 miles west by south of the General Post-office, London, by the coach-road through Maidenhead, Henley-on-Thames, and Wallingford.

Wantage was a place of some importance in the time of the Saxons, when it formed, with the neighbouring lands, part of the patrimony of the West Saxon kings, who had a residence here. It was the birthplace of King Alfred the Great.

The parish of Wantage has an area of 7530 acres, and comprehends the town of Wantage and the hamlets of Charlton and Grove. It contained, in 1831, 729 inhabited houses, 36 uninhabited houses, 748 families, and 3282 persons; rather less than a third of the population was agricultural. The town stands at the intersection of the London road with the Great Western road, with a cross-road from Oxford to Hungerford: the streets are irregularly built, and contain but few good houses. The parish church, dedicated to St. Peter and St. Paul, is an ancient cross church, with a tower rising from its intersection: it contains some ancient tombs and monumental brasses, partly of the Wantewarren family. There is an ancient building of Norman architecture, called by Leland a church, standing near as a school-house in the ancient mansio. Wantage was placed on the route by the Geseps Canal comes up to the town, and on Saturday for pigs, cattle, and
cheese fair, and in the year two fairs for cattle and cheese, one for cherries, and a statute-fair. There are two banking-houses.

The living is a vicarage, of the clear yearly value of 50s., with a glebe-house; in the rural deanery of Abingdon, in the archdeaconry of Berkshire, and diocese of Oxford. The perpetual curacy of Grove in the parish, of the clear yearly value of 75l., with a glebe-house, is in the gift of the vicar. There are places of worship for Independents, Baptists, and Wesleyan Methodists.

The parish, in 1831, nine day-schools, with 231 children, namely, 106 boys, 56 girls, and 69 children of sex not stated; making about one in fourteen of the total population under daily instruction. One of the day-schools, with 50 boys, is partly supported by subscription. There was at the same time one Sunday-school with 80 boys and 90 girls. Bishop Butler, author of 'The Anatomy of Religion,' and Isaac Kimber, a dissenting minister and an historical and biographical writer of some distinction, were natives of Wantage.

(Lysons's Magna Britannia; Beauties of England and Wales; Parliamentary Papers.)

WAPENTAKE (from the Saxon weapen, arms, and tac, touch, or betach, yield) is a term which prevails in Yorkshire. It indicates a territorial division like the hundred of other counties. [Shire.]

The word is derived from the habit which our Saxon ancestors had of attending with their weapons the meetings of their tribes, and which was even canonized for the administration of justice or to decide on peace or war. This circumstance, inseparable from the assembly, gave a name to the meeting and to the district whose inhabitants were convened. Various explanations, all however connected with usual arms, are given to the last syllable. By some it is supposed to mean the touch or rustling of their arms, by which the assembly was wont to signify its opinion of the matters submitted to it; by others the acceptance by the lord of the tenants' arms in token of their submission to him. There are the two solutions quoted by Spelman. Others however say that the word denotes the custom which the vassals had of touching the spear of the lord as a mark of homage; and this seems to be the explanation most generally adopted. (Spelman, Wapentackum et Wapengetachum; Cowell.)

WAPELI. [DEEK, vol. viii., p. 350.]

WAPPING. [LONDON.]

WARASDIN, one of the three counties (Warasin, Kreu, and Agram) into which the Austrian kingdom of Croatia is divided, is bounded on the west and north-west by Styria, on the north-east by Szalad (a county of Hungary), on the east by Kreuz, and on the south by Agram. Its area is 720 square miles, and the number of the inhabitants 165,450. (Statist. Chart. Croat.)

The face of the country is an undulating plain, traversed by a branch of the Austrian chain from west to east, which divides it into two nearly equal parts. The principal rivers are the Drave, which runs along the northern frontier, draining the country from Hungary; the Scutla, which separates Croatia from Styria; and the Krapena, which forms the frontier between the cantons of Warasdin and Agram. More than a third of the country is covered with forests. The plain near the Drave produces more than sufficient corn for the consumption of the inhabitants, but the mountainous and larger portion seldom yields enough. The natural productions are corn (especially maize), milk, tobacco, fruit of different kinds, especially plums, and timber. There is a very good breed of horned cattle, and great numbers of swine, fish, bees, and game. The minerals are, besides marbles of different kinds, a very thick stratum of native sulphur at Radoboli, and gold, which is obtained by washing from the Drave, to the value of 1200 to 1800 ducats annually. Blumenbach moreover says that the gold-washing in the Drave has ceased. The climate is pleasant and healthy.

WARASDIN, the capital, or county town, is situated on the right bank of the Drave, over which there is a remarkable wooden bridge. It lies in 46° 18' N. lat. and 16° 22' E. long., in a plain which is enclosed on the east and west by mountains. It is a well-built but not very lively town, and contains several large and handsome edifices, among which are the cathedral, a Jewish church, a Jew's hospital, the senate-house, the residence of the bishop and chancellor, and some convents. There are likewise a Roman Catholic gymnasium, a convent of Ursaline nuns, a girls' school and hospital, and, within these few years, a philharmonic society. Good wine is produced in the environs. Some tobacco is manufactured in the town, and there are some vinegar-breweries. The suburbs are extensive, and contain some good buildings. Warasdin was formerly fortified, but the fortifications have fallen into decay.

(Blumenbach, Neuestes Gemäle der Oesterreichischen Monarchie; Jenny, Handbuch; Hasel, Handbuch; Die Oesterreichische Nationalbibliothek.)

WARBECK, PERKIN. [HENRY VII.]

WARDERG. [SWEDEN.] — WARBLERS. [SYLVIIDAE.]

The true Warblers were arranged by Linneus under his genus Motacilla. They comprise a smaller single group.

Mr. Nuttall gives a concise but comprehensive general account of this interesting group.

The bill, lie remarks, is slender, straight, awl-shaped, higher than it is wide at the base. The bill is relatively short in proportion to the head, the culmen being less than the fourth longest; scapulars considerably shorter than the quill feathers.

Female generally distinguished by a less vivid plumage.

Young usually assuming the adult plumage after the first moult. Some species moult twice in the year.

Mr. Nuttall further observes that species of this mercurous race are spread over the whole globe. They usually have a general sprightly, in some cases iridescent, plumage. The males, in many cases, have an incessant activity, in accordance with the subtilities of their flying insect prey; they therefore approach both in habit and character the Flycatchers, Vireos, Thrushes, Saxicolous, and Wrens so nearly, that it is rendered difficult to which of these genera they ought to be referred. They principally inhabit forests or thickets, and some affect watery situations or reed-marshes. Many are remarkable for the melody of their song, and the sprightliness of their air, which in the period of incubation they almost incessantly counter. Those coo in the autumn, or winter, or even in the spring, are characterised for his powerful, varied, and pathetic lay, as well as the humble but tuneful Robin Redbreast, belong to the highly vocal genus (Syliva, Lath.); and though many species seek out the arctic solitudes in which to waste their melody or soothe alone their mates, at other seasons may be observed among the more familiar tenants of our gardens, groves, and orchards. Living almost exclusively on the winged insects of summer, which they destroy, or, on the autumnal winds, which are its true or false friends as such. But how well this bird is taken to the south in autumn, and pass their winter in the warm or tropical regions. Some exist more or less generally on berries in the latter end of the year, and consequently find means thus to winter in the milder climates which they are sometimes exposed to from severe extremes. Among many of the species the more active and vigorous male, intent on the object of his migration, precedes the arrival of the female.'

EUROPEAN WARBLERS.

The following are figured and described in Mr. Gould's 'Birds of Europe': —

*Wheatears.*

Sarciza cachinnans. — The Black Wheatear.

Geographical Distribution. — Southern Europe and Africa.

Sarciza leucoma. — The Pied Wheatear.

Geographical Distribution. — Northern Europe, and probably Northern Asia.

Sarciza oenanthe. — The Wheatear.

Sarciza stagnazza. — The Russian Wheatear.

Geographical Distribution. — South of Italy, Dalmatia, and Greek Archipelago; rare in the north of Italy, not recorded from the central European districts.

Sarciza aurita. — Black-eared Wheatear.

Geographical Distribution. — Hillier parts of south of Europe. Common in the north of Italy than the Russian Wheatear. Frequent in the Neapolitan States and Sardinia.
The Whinchats.

Whinchats.

Saxicola rubicola.

Description.—Old Male.—Summer Plumage.—Head, throat, back, and small coverts of the wings perfect black; but each feather very finely bordered with ruddy brown; a great white spot on the sides of the neck, on the upper part of the wings, and on the rump. Breast deep ruddy; lower parts very bright ruddy; wings brown bordered with brighter brown; base of all the tail-feathers white, the rest of a blackish brown. Length four inches four or five lines.

Male after the Autumnal Moults.—Wider ruddy borders at the end of the feathers on the throat; those of the nape and the back fringed with large borders of that colour; breast bright ruddy, the rest of the lower part of the body clear Isabella colour; wider borders on the quills, and the end of the tail ruddyish.

Female.—Upper parts blackish brown with borders of yellowish ruddy; wings and tail-feathers brown bordered with yellowish ruddy; throat black, with small whitish and ruddyish spots; the white space on the sides of the neck and of the upper part of the wing less extended; ruddy colour of the breast less vivid.

Young Males before their Second Moults like the old female.

Young at their Departure from the Nest.—Feathers of the upper parts greyish brown; all terminated by a small whitish spot.

After the autumnal moults all the individuals have brown ruddy colour on the head and the back; this colour occupying solely the fine points of the bars, they by exposure and friction cause in the spring the black colour of the middle of the feathers to appear. (Tomm.)

This is the Traquet rubicole and Moteur Traquet of the French; Saltabasone, Zompiscard, and Sallipalolo of the Italians; Schwarzkehliger Steinenschmäuer of the Germans; Clochder y cerrig of the ancient British; and Stonechat, Stonechatter, Stonemith, Stonemik, Stonecirk, and Moor-wistle of the modern British.

Geographical Distribution.—Russia, Germany, France, Provence, Italy, Smyrna, Japan, the Deccan, the banks of the Ganges, the mountain-chain of Upper Hindostan, Senegal, and South Africa (Cape). England, Ireland, and Scotland.

Habits, &c.—Though several of this species remain through the winter months, the general body quit the British Islands in autumn, nor do they return till the spring is forward. It is to be observed, however, that the parties which are observed in this country, and are called Robins, are generaly seen in the open tracts which are their favourite quarters, and, and wind and weather permitting, there are to be seen almost ever in motion, now on a stone, now on a bush, from which they dart to seize the passing insect and then return. Although their song, which is given on the wing, is short, it is peeping; and they are in a degree mocking birds, being no bad imitators of the song of others. Besides insects, worms are acceptable food to them; and for these they may be frequently seen foraging on the ground.

The nest, which is of considerable size in proportion to the bird, is framed in the beginning of April on the ground or some dwarf bush. Externally it is fabricated of moss and grass; and a few fine bents, hairs, and feathers form the lining. The eggs, which are laid from the middle of April to the third week in that month, are made with the very rudest materials, somewhat of a greyish tint, finely dotted with obscure reddish brown at the large end.

When the young are hatched—that is, about the middle of the month—the old mates excepting the female, become very bold. They have a constant clamour, and put in practice many a ruse to deceive the schoolboy and draw him from their nest.

Redstarts.

Phoenicura rubicilla. The Redstart.

Phoenicura tithys. The Black Redstart. Rare in Britain.

We select the Common Redstart, Motacilla phaenicurus, Linnaeus, as an example.

Description.—Old Male.—Forehead and eyebrows pure white; a small black spot on the tip of the bill, space between that and the eye, throat, and upper part of the neck deep black; head and upper part of the back bluish ash; breast, sides, rump, and lateral tail-feathers brilliant ruddy; abdomen whitish, lower coverts of the tail deep ruddy, two miles feathers brown.

The Female (which may easily be confounded with that of Phoenicura suecica, the Blue-throated Warbler) with the upper parts grey strongly shaded with rusty; great wing-coverts, breast, and sides with ruddy yellow; throat, breast and sides rusty, belly whitish, under tail-coverts paler rusty. The very old have the throat blackish, spotted with rusty.

Young Males of the Year.—No white on the forehead; black of the throat broken with whitish lines; ruddy colour of the breast varied with white; upper parts rusty ash, tail coverts and feathers bordered with white.

Young Females.—These may be distinguished from the nightingale by the black bill and feet, and the two middle tail-feathers, which are always blackish-brown.

Belon is of opinion that this is the phoenicurus Aristotelis (Hist. Anim. ix. 40). It is the Corosolo, Codoroastro, Culo ranzo, and Culo rosso of the Italians; Rossignol de mar à gueule blanche of the French; Schwarzkehliger Anger, Schwarzköhllein, and Garten-Rothschleicher of the Germans; Gekraagde Roodstaart of the Netherlanders; Roosje of the Swedes; Roedstiert of the Danes; Blodfugl of the Norwegians; Rhonei gec of the antique British; Redtail, Brantail, and Firetail of the modern British.

Geographical Distribution.—Denmark, Norway, Sweden, Russia, Europe generally, particularly Holland, France, Provence, Spain, and Italy; Portugal, and to the south-east of that locality, Germany, and Japan.

In Britain it arrives about the middle of April, penetrating as high as Sutherlandshire in Scotland. Pennant says that it extends no farther west than Exeter, but it has been seen in the eastern portion of Cornwall, and is far from uncommon in the western part. The ancient British name above given, from Pennant, indicates that the bird must have been formerly known in Wales, and certainly is now, and has even been found near Belfast in Ireland.
appears to be a singular instance. They quit England, generally, at the commencement of September.

Habits, &c.—This is a sweet and indefatigable singer, and has been heard in a wild state as late as ten o'clock at night, and as early as three o'clock in the morning. The skirts of woods, lane and meadow hedge-rows, orchards, gardens, the old ivied-wall of a ruin, are all favourite haunts. The male shows himself, as if proud of his pretty plumage, whilst he is uttering his soft, sweet song, vibrating his tail the while, on some low branch of a not high tree or weather-beaten stone, nor does his music cease as he flies to another station to continue his strain.

A crevice in a wall, a hollow tree, a nook in a building sheltered behind a limb of antient ivy, or even of an old fruit-tree trained against it, sometimes a hole in the ground, receives the nest, the outside of which is rough and rich with moss, and lined with hair and feathers. Four, six, and even eight greenish-blue eggs are deposited, and the first brood, for there are generally two in a season, are frequently fledged by the second week in June. The food consists of worms and insects, fruit, and berries. Bechstein speaks highly of its attractive qualities in plumage, gesture, and song; and says it will add to its natural notes parts of the songs of other birds. He tells us that those which built under his roof imitated tolerably the chaffinch that hung in a cage at his window; and his neighbour had one in his garden that repeated the strains of a black-cap which had its nest near.

In captivity Redstarts become so tame that they will take a meal-worm from the hand. Sweet says that, when kept in confinement, he considers this bird the most sensible and, if brought up from the nest, the most attached of all small birds; but he adds that it may be deemed the most tender of all the tribe. It is, he observes, a real mocker, and, if bred up from the young state, will learn the note or call of almost any other bird: it will also learn a tune, and will sing by night as well as by day, as long as a light is kept burning. He had one that whistled the Copenhagen Waltz.

The Redstart.

The portrait of Oiseaux has the following quatrains under the cut of this Nightingale:

*Waltz.*

*Notwithstanding the censure involved in the last line and a half, however, the Redstart is a very charming songster. In comparison with the nightingale, every other bird's song must fade.*

*Phoenicura suecica, the Blue-throated Warbler. [Breast.]*

*Robins. Erythaca rubecula, The Redbreast. Though the subject be very tempting, we should not be justified in occupying space in this work by a detailed description of this familiar bird, dear to infancy and old age. Belon makes it the *Epithetos* of Aristotle (ix. 49), and not without reason. Geographical Distribution.—Norway, Denmark, Sweden, Iceland (rare), Orkney, Scotland, England, Ireland, and Wales (where it is called *Yr Hobi goch* and *Brogoch*), the temperate and warm parts of Europe, plentiful in Spain and Italy, North Africa, Smyrna, Trebizond. The following quatrains appear under the figure of this species in the Portraits above cited.*

*As Remoulant de moraille ressemble* 
La Georce-rouge, en chans armoinence. 
Elle en lyre appelle joyeusement 
Luy en son supplice de nous assouvaise.*

 Accentor.

*Accentor alpinus, The Alpine Accentor. Geographical Distribution.—The Alpine districts and mountainous parts of the continent of Europe. Switzerland and Tyrol have it in abundance. In Britain its appearance is comparatively rare.*

*Accentor modularis—Common Hedge Accentor, a Hedge Warbler. Hedge Sparrow of many districts; *Lotul g y gwyn* of the ancient Britons. This poor little songster's nest is generally the first that the urchin takes; the eggs are azure, and are generally laid very early, and before the leaf is sufficiently out in the hedge-row, one of its most frequent localities, to hide the nest.*

*Geographical Distribution.—Great Britain. Central Europe.*

*Accentor montanillus, Mountain Accentor. Geographical Distribution.—Eastern Central Europe and Asia, Eastern Siberia, the Crimea, Neapolitan States, Dalmatia, and Central Hungary.*

Locustelles.

*Locustella fluviatilis, The Reed Locustelle. Geographical Distribution.—Rare in Western Europe. Frequent in Austria and Hungary, and of common occurrence near Vienna, in the gardens of the little isles in the Danube.*

*Locustella avicula, The Bruke Locustelle. Geographical Distribution.—England and Ireland, arriving in April. Austria, Hungary, Italy, South of France, Holland (not common), Germany (north and northeast), Saxe (rarely, as a passenger).*

*Locustella luscinoides, Willow Locustelle. Geographical Distribution.—South of Europe. Specimens have been taken in England (Cambridgeshire, 1836). Winter retreat Africa, probably the urchin takes; the eggs are azure, and are generally laid very early, and before the leaf is sufficiently out in the hedge-row, one of its most frequent localities, to hide the nest.*

*Geographical Distribution.—South Russia.*

Salicarias.

*Salicaria turboidea, Great Sedge Warbler. Geographical Distribution.—Holland abundantly, Lowlands of France, even near Calais.*

*Salicaria olivetorum, Olive-trees Salicaria. Geographical Distribution.—Ionian Islands; Zante. (Sri Lanka.)*

*Salicaria arundinacea, Reed Wren. Geographical Distribution.—Temperate Europe. British Islands. Holland, Germany, France, rare in the south of Europe.*

*Salicaria palustris, Marsh Warbler. Geographical Distribution.—Central Europe. Frequent on the banks of the Po and Danube. Parts of Switzerland, Germany, and Holland.*

*Salicaria argentea, Sedge Warbler. Britain generally and the Continent. Very abundant in France, Germany, and Holland.*

*Salicaria melanopogon, Moustached Warbler.*
The Dartford Warbler is, generally speaking, insectivorous, but fruits do not come amiss to it, that is, such berries as it may find near its retreats.

**Noteworthy**: This is the *Pitte-chou de Provence* of the French; the *Maggianna* of Saxi, and *Proverne Sanger* of Meyer.

**Geographical Distribution**: Southern Europe; the countries that border the Mediterranean, Spain and the south of Italy, but the Prince of Canino and Musigiano notes it as rare, and as found in summer in mountainous situations. It is comparatively scarce in Germany and Holland. Permanent in England, but not generally diffused. Frequent in the neighbourhood of London, and also at Bagshot, Chobham, and their vicinities. Devonshire, Cornwall, and Berkshire possess it also.

**Habits**: This pretty warbler is a very hermit in its love of retirement and seclusion. The furze-brake and tangled heath are its favourite haunts, and well it knows every labyrinth of every bush on the breezy common where it takes up its abode. Mr. Gould observes, that its form closely alludes it to the Superb Warblers (*Melurus*) of New Holland, while its relationship to the Common Whitethroat is strikingly apparent. With reference to its secluded habits, the same author well remarks that in the spring it becomes more lively and more frequently visible, rising on quivering wing above the tops of the furze, and uttering a hurried babbling song, much after the manner of the Whitethroat; at these times it erects the feathers of the head into a crest, and distends the throat, exhibiting many attitudes and gesticulations.

Dry stalls and grass interwinned with fibres of plants and roots form the nest, which is generally snugly hid in the very heart of a thick furze-bush not far from the ground. Eggs greenish-white, with brown speckles and ash spots, and thus resembling those of the Whitethroat.

The Dartford Warbler is, generally speaking, insectivorous, but fruits do not come amiss to it, that is, such berries as it may find near its retreats.
African Warblers.

Many of the warblers of Europe make Africa, especially the north, their winter-quarters. The Stonechat, as we have seen, extends to that continent, and Mr. Swainson, in his 'Birds of Africa,' records another, Saxicola fractalis, the White-fronted Stonechat, which is entirely uniform black, with the front of the head snowy. Whether this spot is a sexual distinction peculiar to the male, or whether it is common also to the female, is yet, according to Mr. Swainson, to be discovered.

American Warblers.

Although the American Warblers are not gifted generally with much power of song, the species are very numerous. The Prince of Camino and Musignano, in his 'Specchio Comparativo,' enumerates thirty-four American species of Sylvis, four belonging to the subgenus pruni, and one of Saxicola (sialia). In his 'Birds of Europe and North America,' the same noble author records forty-five American species of Sylvia warblers, belonging to the genera Parula, Trichos, Verminus, Sayia, Sylvia, and Cullivora. The bulk of these species are Sylviae. He also notices three species of Sialia (American).

We select, as an example, Sylvia coronata. The Yellow-crowned Warbler, or Myrtle Warbler.

Description.—Summer Plumage.—Blackish slate-colour, streaked with black; beneath white; breast spotted with black; crown, sides of the breast, and rump yellow; wings bisected with white; tail black; three lateral tail-feathers spotted with white.

Winter Plumage—edged with brownish olive, the yellow of the crown partly concealed by a margin of the same oliveaceous hue; no black on the head or face. Young brood, the young much paler and nearly without black.

Length from five to six inches; alar extent from eight to nine.

Geographical Distribution and Habits.—Arrives in the Middle and Northern states of the Union from the south towards the end of April or beginning of May, and then probably passes north to breed. In August they reappear, in those states, and remain about the gardens and woods till about the end of November, feeding almost exclusively at this period on the myrtle-wax berries (Myrica ereryfera) or those of the Virginian Juniper. These, says Mr. Nuttall in continuation, 'other late and persisting berries, and occasional insects, constitute their winter food in the Southern states.' Considering the numbers, in the swamps and sheltered groves of the sea-coast, they pass the cold season. In fine weather, in the early part of October, they may be seen at times collecting grass-hoppers and moths from the meadows and pastures, and, like the Blue-Bird, they often watch for the appearance of their prey from a neighbouring stake, fence, or fence-rail; and at this time are so familiar and unsuspicous, particularly the young, as fearlessly to approach almost within reach of the silent spectator. At the period of migration they appear in an altered and less brilliant dress; the bright yellow spot on the crown is now edged with brownish-olive, so that the prevailing colour of this beautiful mark is only seen on shielding the feathers with the hand; a brownish tint is also added to the whole plumage; but Wilson's figure of this supposed autumnal change only represents the young bird. The old is, in fact, but little less brilliant than in summer, and I have a well-founded suspicion that the wearing of the edges of the feathers, or some other secondary cause, alone produces this change in the livery of spring, particularly as it is not in any sexual distinction. While feeding, they are very active, in the manner of Flycatchers, hovering among the cedars and myrtles with their wings only partly opened; but when satisfied with gleaning food. In spring they are more tidy, busily, and restless. Of their nest we are wholly ignorant. When approached, or while feeding, they only utter a feeble plaintive tsey of alarm. This beautiful species arrives here about the 7th or 8th of May, and now chiefly frequents the orchards, uttering, at short intervals, in the morning, a sweet and varied, rather plaintive warbling, resembling in part the song of the Summer Yellow-bird, but much more the farewell, solitory, autumnal notes of the

Robin Red-breast of Europe. The tones at times are the so ventriloquial and variable in elevation, that it is often easy to ascertain the spot from which they proceed. While thus engaged in quest of small caterpillars, it seems almost insensible to observation, and familiar searches for its prey, however near we may approach (Manual).

The Summer Yellow-bird, Sylviae olivacea, above noticed, is remarkable for its skilful prevention of the designs of the Cow Treepip (Motacilla). 'This is amusing,' says Nuttall, 'to observe the sagacity of this little bird in disposing of the eggs of the migratory and parasitic Cow Treepip. The eggs, deposited before the laying of the rightful tenant, too large for ejection, is ingeniously incarcerated in the bottom of the nest, and a new lining placed above it, so that it is never hindered to prove the dragon of the brood. Two instances of this kind occurred to the observation of my friend Mr. Charles Pickering, and last summer I obtained a nest with the adventitious egg about two-thirds buried, the upper edge only being visible, so that in many instances it is probable that this species escapes from the unpleasant suspicion of becoming a nurse to the sable orphan of the Cow-bird. She however acts faithfully the part of a foster-parent when the egg is laid after her own.

Australian Warblers.

The New Holland Wrens (Miliarus) may be considered as the Warblers of that fifth quarter of the world [Wrens]; but there are also some Sixtocline forms which should be here noticed. Such are the Epithianuree, of which the reader will find an interesting account under the titles of Epithianura albofrons, Epith. aurifrons, and Epith. triatrachus, in Mr. Gould's grand work on the 'Birds of Australia' now in course of publication.

We select, as an example, Epithianura albofrons, White-fronted Epithianura.

Description.—Male.—Forehead, face, throat, and all the under surface, pure white; occiput black; chest crossed by a broad crescent of deep black; the points of which run up the sides of the neck and join the black of the occiput; the upper surface dark grey with a patch of dark brown in the centre of the back feather; wings dark brown; upper tail-covers black; two central tail-feathers dark brown, the remainder dark brown, with a large oblong patch of white on the inner web at the tip; irides in some beautiful reddish-buff, in others yellow with a slight tinge of red on the outer edge of the pupil; bill and feet black.

Female.—Crown of the head, all the upper surface, wings and tail, greyish brown, with a slight indication of the oblong white spot on the inner webs of the latter; throat and under surface buffy-white; a slight crescent of black on the chest. (Gould).

Locality and Habits.—Mr. Gould first met with this
WAR

WAR

species in a state of nature on the small islands in Bass's Strait, where, he says, it had evidently been breeding, as he observed several old nests in the Barilla and other stunted bushes which clothe other isolated spots, particularly chalky and green islands immediately contiguous to it in Flinders. He did not observe it in Van Diemen's Land or to the southward of the localities above mentioned. He thinks however that it extends over the whole of the southern portion of the Australian continent, for he has specimens which were killed at Swan River, in South Australia, and in New South Wales. The extent of its range northwards is not, he remarks, known. He had never seen examples from the north coast.

It is, observes Mr. Gould, 'a most sprightly and active little bird, particularly the male, whose white throat and banded chest render him much more conspicuous than the sombre-coloured female. As the structure of its toes and lengthened tendons would lead us to expect, its natural province is the ground, to which it habitually resorts, and evidently excises a preference to spots of a sterile and barren character. The male, like many of the Saxicoline birds, frequently perches either on the summit of a stone or on the extremity of a dead and leafless branch. It is rather shy in its disposition, and when disturbed flies off with considerable rapidity to the distance of two or three hundred yards before it alights again. I observed it in small companies on the plains near Adelaide, over the hard clayey surface of which it tripped with amazing quickness, with a motion that can neither be described as a hop nor a run, but something between the two, accompanied by a bobbing action of the tail.'

Mr. Gould adds that nothing is known of the nidification of this species. As little seems to be known of the rare Tri-colored Ephialtnura, the brilliant scarlet of whose plumage renders it a most striking object.

Ephialtnura albifrons. Male. (Gould.)

WARBURG, the chief town of a circle of the government of Minden, in the Prussian province of Westphalia, is situated on the river Dylem, in a very fertile plain. It is divided into the old and the new town, has six gates, two market-places, two churches, one chapel, one Dominican convent, and a Roman Catholic gymnasium. There are 3200 inhabitants, who have manufactories of linen and tobacco, some breweries, and a brisk trade, especially in corn, cattle, and iron. There are frequent pilgrimages to the chapel of St. Ermusus. Near the town are the ruins of the Deessenberg, which are worthy of notice as a remarkable monument of the times of chivalry.

(J. C. Müller, Geographisch-statistisch-geographisches Werckbuch des Preussischen Staates.)

WARBURTON, WILLIAM, a very distinguished English prelate, was born at Newark, 24th December, 1698, and was the elder of the two sons of Mr. George Warburton, an attorney of that place, who held the office of town clerk, and of Elizabeth, daughter of Mr. William Hobman, one of the aldermen of the borough. The family was originally from the county of Chester. Warburton's grandfather, also an attorney, who had taken the royalist side in the civil war, was the first of them that settled in Newark.

Warburton lost his father when he was only eight years old; so that the care of his education fell upon his mother, who was left with the charge of three daughters besides two sons, and who survived her husband. Being designed for the profession of his father and grandfather, he received the usual grammar education, first at the school of Okehain in Rutlandshire, under Mr. Wright, who afterwards became vicar of Cambden in Gloucestershire, then at that of Kidderminster and Malvern, to which last place his mind was especially turned. On leaving school in 1715, he was placed in the office of Mr. Kirke, an attorney, at East Markham in Nottinghamshire, with whom he continued till April, 1719, when he set up business for himself at Newark. But a love of reading and study had early taken possession of him; his professional success, probably impeded by these tastes, is supposed not to have been considerable; and at length, having made up his mind to enter the church, he received deacon's orders from Dawes, Archbishop of York, in 1723.

He now also published his first literary performance, a 12mo. volume of Miscellaneus Translations, in prose and verse, from Roman Poets, Ovatus, and Historians. In 1724 he orders from the printers a volume of his works at London, and by the interest of Sir Robert Sutton, to whom he had dedicated his book, was instituted to his first pre- ferment, the small vicarage of Gresley in his native county. This was in the end of 1724, and in the same year he went to London, and formed what we may call his first literary connexion, which was with Theobald, Concenœ, and others, then chiefly held together and banded into a sort of con- federation by their common hostility to Pope, under the screen of whose satire they had most of them to be protected. Warburton entered into all the animosities of his associates, and in particular was unfortunate enough to induce an epistle to Concenœ, dated January 2nd, 1726 (that is, 1727), in which he said that Dryden borrowed for want of leisure, and Pope for want of genius, and which, much to his annoyance, was published long afterwards, in 1766, by Akenside the poet, whom he had offended, from the original, discovered in 1756, by Dr. Gavin Knight of the Brit- ish Museum, in setting up a house in Concenœ Court, Fleet Street, where it is supposed Concenœ had lodged. (See Akenside's 'Ode to Thomas Edwards, Esq.,' and Bucke's 'Life of Akenside,' pp. 149-171.) Warburton's connexion with Theobald at this time also led him to furnish some notes to that gentleman's edition of Shakspere, which ap- peared in 1733.

In 1727 Warburton published, in 12mo., his 'Critica and Philosophical Enquiry into the Causes of Prodigies and Miracles,' and the same year his only contribution to the literature of his original profession, a treatise entitled The Legal Judicature in Chancery stated. The latter work appeared anonymously, and is stated to have been undertaken at the particular request of Samuel Burroughs, Esq., afterwards a master in chancery, who put the materials into Warburton's hands. In Reed's 'Law Catalogue, London, 1809, it is described as 'said to be written by Master Speier, but generally ascribed to Lord King.'

In April, 1728, Warburton, by the interest of Robert Sutton, was placed in the King's list of masters of arts for creation at Cambridge, on his majesty's visit to the university; and in June the same year he was presented by the same friend and patron to the rectory of Woot or Brant Broughton, near Newark. His next publication of importance, and the first which made him generally known, did not appear till 1736—his famous treatise enti- tled 'The Alliance between Church and State,' or, the Necessity and Equity of an Established Church, a work of Law demonstrating what was from the moment of its publication, to be very generally accepted by moderate politicians, and which made them as the surest vindication of national establishments. It was described by Bishop Wheeler as a book 'of very great merit after its appearance, as of the year 1734.'
that are to be found, perhaps, in any language, of scientific reasoning applied to a political subject.

J. D. the following year, 1738, Warburton published the first volume, containing the first three books, of his great work, ‘The Divine Legation of Moses demonstrated on the Principles of a Religious Deity, from the Omission of the Doctrine of a Future State of Rewards and Punishments in the Jewish Dispensation.’ It immediately, as was to be expected, raised a storm of controversy, which lasted for many years, and in the course of which the author had to defend himself against Drs. Stebbing, Sykes, Pococke, R. Grey, Middleton, and other assailants, in some respects a most unreasonable as well as with the common object of their attacks. Warburton treated them all, Middleton alone excepted, much as a schoolmaster might treat so many of his pupils who should have ventured into a dispute with him or to clamour against his authority.

The leading idea of the ‘Divine Legation’ is, that so important a doctrine as that of a future state, which must be regarded as the chief natural cement and bond of human society, could not possibly be dispensed with the scheme of mere human legislation, and that hence the Mosaic dispensation, in which, according to Warburton’s view, it is omitted, must have come from heaven, and must also have been maintained in a peculiar manner by a divine influence. This influence had, or had, or had not, this view was at least undeniably a new one; and it was developed by its author with ingenuity, a fulness and variety of learning, and an unflagging animation. It is a work which never had been written before, and perhaps has not been exhibited together in one English theological work. But in truth mere theological discussion forms only a small portion of the book; the author is continually making excursions from the straight path of his subject, and in this way the course of their journey, together, over some of the most interesting fields of literature and philosophy.

A second edition of the first volume of the ‘Divine Legation’ was called for before the end of the year in which it was printed. The second volume, containing the fourth, fifth, and sixth books, appeared in 1741. The first volume, enlarged and divided into two volumes, was published for the fourth time in 1756; and a new edition of the second, similarly enlarged, appeared in 1756. In a third edition, which appeared in 1763, this second part of the work was extended to three volumes; so that the whole now consisted of five volumes.

Meanwhile the author had also been engaged in a various other labours and had built up his fortunes in more ways than one. Shortly after the appearance of his first volume, in 1738, he was appointed chaplain to the Prince of Wales. The following year six letters which he published in ‘The Works of the Learned,’ in defence of the theory of Prophecy, and the attacks of M. de Crouzaz, introduced him to the acquaintance of Pope, who proved, for the few years that he lived, this the steady and zealous friend of his voluntary champion. A seventh letter, by the author of the ‘Divine Legation,’ contained an apology for the first of his published in ‘The Works of the Learned,’ completed the vindication of the poem in June, 1740; and when Pope died, in May, 1744, it was found that he had left Warburton half his library, with the property of all such of his works already printed as he had not otherwise disposed of, and all the profits which should arise from any edition to be printed after his death. In 1749, upon Lord Bolingbroke, in the preface to his ‘A Letter to a Patriot King,’ having charged his late friend Pope with having clandestinely printed an edition of that work some years before his death, its author’s leave or knowledge, Warburton is believed to have been the writer of ‘A Letter addressed to Bolingbroke, which immediately appeared in vindication of the deceased poet, and which Bolingbroke soon afterwards repied to in what he called ‘A Plain Answer to Mr. Warburton,’ and in the third volume of his ‘Letters,’ added to the above, on Warburton and Bolingbroke had once been introduced to each other by Pope, but parted with feelings of mutual disgust; and it is probable that Pope’s intimacy with Warburton in his last days mainly contributed to alienate him from his older friend.

One of the most important services which Warburton owed to Pope, was his introduction to the house of Ralph Allen, Esq., of Prior Park, near Bath. This led to his marriage, in September, 1745, with Allen’s niece, Miss Gertrude Tucker, in whose right, on Allen’s death, in 1751, he became proprietor of Prior Park.

On Sunday evening, which he published from time to time must be passed over without notice. It may be mentioned, however, as illustrating the versatility of his powers, that one of his productions in 1742 was a ‘Sertation on the Origin of Books of Chivalry,’ which appeared in the second volume of his ‘Letters’ to Jarvis’s translation of ‘Don Quixote,’ and which Pope soon after told him he had immediately recognised to be his, exalminating, before he had only over two paragraphs of it, ‘Art Eramus sat Diabolosa.’ The same year he published ‘A Critical and Learned Enquiry into the Origin of the Phrases, Fiery, Devil, Fire, and Devil;’ and he also persuaded Pope to substitute Colley Cibber for Theobald as the hero of the ‘Dunciad,’ and to complete that poem by the addition of a fourth book.

In August 1746, Warburton’s reputation was now very great, was unanimously elected preacher of Lincoln’s Inn. Besides many controversial tracts and other minor pieces, the following eight or nine years produced his edition of Shakespeare, in 8 vols. 8vo., Lord Hurd’s ‘A performance of the British Saxon Chronicle,’ published in 1749; ‘The Life, and Writings, and Character of the Author.’ Meanwhile the late Dr. Parr, with no friendly purpose, had supplied the deficiencies of Hurd’s collection by the publication in Legems of the third volume of Campion’s Life, and a Warburtonian (Hurd himself), not admitted in their work. An 8vo. volume of ‘Letters from Warburton to one of his Friends’ (Hurd), appeared in 1749; and in 1814 another 8vo. volume was published by Mr. Kilve, containing ‘Life and Remains of Bishop Warburton.’ Many letters of Warburton’s, and also anecdotes of his life, which have not been collected, are to be found scattered over various publications. A portion of his correspondence which much known is contained in the ‘Account of the Life and
Ward, John, LL.D., was born in London, in 1679, and was one of the fourteen children of a dissenting minister of the same name, who was originally from Tysoe in Warwickshire, and died in 1717, leaving of his numerous family only this son and a daughter. Ward held the situation of clerk in the navy-office till 1710, when he opened a classical school in Tenter Alley, Moorfields. His first publication was an attempt at a uniform motion in some part of the system of a planet; and being capable of affording facilities in the determination of the true from the mean anomaly, it was adopted by other astronomers in that century; it has however no foundation in fact, and has been long since abandoned by astronomers.

His first publication was an attempt at a uniform motion in some part of the system of a planet; and being capable of affording facilities in the determination of the true from the mean anomaly, it was adopted by other astronomers in that century; it has however no foundation in fact, and has been long since abandoned by astronomers.

Ward, John, LL.D., was born in London, in 1679, and was one of the fourteen children of a dissenting minister of the same name, who was originally from Tysoe in Warwickshire, and died in 1717, leaving of his numerous family only this son and a daughter. Ward held the situation of clerk in the navy-office till 1710, when he opened a classical school in Tenter Alley, Moorfields. His first publication was an attempt at a uniform motion in some part of the system of a planet; and being capable of affording facilities in the determination of the true from the mean anomaly, it was adopted by other astronomers in that century; it has however no foundation in fact, and has been long since abandoned by astronomers.
His principal publications, besides the tract already mentioned, were, a Latin translation of Dr. Mead’s ‘Discourse of the Deity,’ which appeared in 1722; a treatise, printed in Latin, on the principles of Punctuation, appended to an edition of the ‘Elementa Rhetorica’ of Vossius, printed at London in 1724; a new and very correct edition, with a learned preface, of Lily’s Latin Grammar, in 1732; an edition of Maximus Tyrius, published in 4to., in 1740, by the Society for the Encouragement of Learning, of which he became a member in 1736; ‘Lives of the Professors of Gresham College,’ folio, London, 1740; a new edition of Camden’s Greek Grammar, 1754; and ‘Four Essays upon the Public System of the World,’ 1766. After his death appeared ‘System of Oratory, delivered in a course of Lectures publicly read at Gresham College,’ 2 vols. 8vo., 1758; and his ‘Discussions upon several passages of the Sacred Scriptures,’ 2 vols. 12mo., London, 1774. He is also the author of many papers in the Philosophical Transactions, and of some in the ‘Archaeologia.’ And his literary assistance was liberally contributed to the publications of several of his contemporaries; such as to Ainsworth’s ‘Monuments KEMPiana,’ 1720, for which he supplied an elaborate dissertation on the Roman As and its parts, an essay on the vases, lamps, rings, and clasps of the ancients, &c. to HORSELEY’S ‘Britannia Romana,’ 1732, for which he wrote an ‘Essay on Peutinger’s Table, so far as it relates to Britain;’ the fourth edition of De Thun’s ‘Tracts,’ 1729; a treatise, called Buckleys three epitapls to Dr. Mead into Latin; to Ainsworth’s Latin Dictionary, both the first and subsequent editions; to the edition of Aelian’s ‘History of Animals,’ published by Abraham Grevius, in 1744; to the edition of Voet’s Maxima Romanorum Juris, published by Principal Wishart, of Edinburgh, in 1751; to PINE’S engraved Horace, 1733-97; &c. There are several letters to and from Dr. Ward in the ‘Original Letters of Eminence’ noted by Sir J. Ellis, printed by the Camden Society, 4to., Lon., 1843.

WARDS, COURT OF. The Court of Wards and Livery was established by the statute 32 Henry VIII., c. 46, to superintend the inquests which were held after the death of any person, whose tennage being by right of his or her husband’s service, for the purpose of ascertaining what land the tenant died seised of, who was his heir, whether the heir was an infant; and thus what rights accrued to the king in the shape of relief, primer assise, wardship, or marriage.

By the famous statute which limited to the members of the first Parliament of Charles II. (12 Charles II., c. 24), the Court of Wards was abolished, together with the feudal rights out of which that court arose. The preamble of the statute states that it had been intermitted since Feb. 24, 1649. [GUARDIAN.]

WARE, SIR JAMES, an Irish antiquarian. His father, Sir James Ware, a native of Yorkshire, went to Ireland in the time of Elizabeth, as secretary to Sir William Fitz-Wil- liam, 1st Viscount Warenne, and in 1568, was subsequently appointed auditor-general for the kingdom, and purchased considerable property in and near Dublin.

James, his eldest son, was born in Dublin on the 28th of November, 1594. In his sixteenth year he was entered at Trinity College, Dublin, and prosecuted his studies there for six years. Immediately after leaving college he married Mary, daughter of John Newman, Esq., of Dublin. By the advice of Ulster he devoted himself to the study of Irish antiquities. During a residence of some years in England on business, he contrived to sequester that primacy with other legacies, and of Sir Robert Cotton, by whose assistance he considerably increased his collection of manuscripts.

On his return to Ireland in 1620, he was knighted by the lords justices; and in 1632, his father dying suddenly, he succeeded both to his estate and the office of auditor-general. He applied himself assiduously to public business; obtained, in 1633, the confidence of Lord Wentworth (afterwards Earl of Strafford), and was by his advice created a member of the Irish House of Commons. In 1639 Sir James Ware was elected a member of the Irish House of Commons. When the rebellion broke out in 1641, he assisted the government not only by his personal services, but also by becoming surety for sums of money advanced to it. His principal objects were the support of the House of Commons, or either of the Popish or Protestant party, occasioned his being sent, in December, 1644, to inform the king, then at Oxford, of the real state of affairs in Ireland. He employed his leisure hours at Oxford in the prosecution of his antiquarian researches, and had the honorary degree of Doctor of Laws conferred upon him by the University.

The vessel in which Sir James Ware returned to Ireland was taken by one of the Parliament’s ships. He underwent an imprisonment of ten months in the Tower of London, and was released by an exchange of prisoners. In 1647 he was one of the hostages for the performance of the treaty by which the Earl of Ormond surrendered Dublin to the Parliament. He was deprived of his office of auditor-general, but allowed to reside in Ireland, till Michael Jones, governor of Dublin, taking umbrage at him, ordered him to transport himself beyond seas into any county he pleased.

He made choice of France, where he landed early in 1649, and continued to reside till 1651, when he obtained a licence from the Parliament to visit London on business. He resided two years in the vicinity of the metropolis, after the close of that period he was allowed to reclaim his estate in Ireland. He continued to lead a strictly private life till the Restoration, when he was reinstated in his office of auditor-general.

In 1661 the University of Dublin elected Sir James Ware one of its representatives. He was offered the title of baronet or viscount, but declined both. The Marquis of Ormond created him first commissioner of excise. He died in Dublin, on the 1st of December, 1666. He left two sons and an only daughter, and created Sir John Ware, 1st baronet, 1674. Sir James Ware’s more important works are—1. De Præsulis Hiberniae Commentarius, Dublin, 1665, fol. He has incorporated into this work two of his Latin tracts; the one containing the lives of the Archbishops of Cashel, and the other the lives of the bishops of Dublin, published in 1628.

2. De Hibernia et Antiquitatibus ejus Disquisitiones, London, 1654-8. Into this work is incorporated hitherto unprinted out of the Censurae monasterii de Ireland. 3. De Hibernia Historia et Antiquitatibus. 4. Renum Hibernicarum Annales, regnantium Henrici VII., Henrici VIII., Edwardo VI., et Maria, Dublin, 1662, fol. The annals of the reign of Henry VII. were first published in 1628. As the last remaining surviving part of Ware’s work, he published, with considerable additions, in 1739-40, by Walter Harris, who married a granddaughter of Sir James. (Biographia Britannica.)

WAREHAM, a market-town and parliamentary borough in the south division of the hundred of Winchfield Blandford in Dorsetshire, 10 miles from Poole, 18 from Dorchester, and 112 from London. It is within three miles of an arm of the sea, which forms a part of the bay called Poole Harbour. A town existed here in the time of the Britons, and it was subsequently occupied by the Romans. Two Saxon kings were buried here, Bathil, king of the West Saxons, and Edward the Martyr, whose remains were afterwards removed to Shaftesbury. The Bishops of Sherborne were created earls of Warwick by the Danes in the time of Alfred. A priory was founded at Wareham in the ninth century, and there are some traces of an ancient castle. The town was once much larger, and the entire area enclosed by the ancient earthworks is said to be one time occupied. But much of it is now covered with market-gardens. The two decayed parishes of St. Michael and St. Peter are now annexed to the parish of Lady St. Mary, and their churchyard is connected with the churchyard of the other persons still living. The three other parishes, Lady St. Mary’s, Trinity, and St. Martin’s, are now united, and form but one parish for ecclesiastical purposes. The church of Trinity parish is used for the national school; that of St. Mary’s is supplied by a curate; Lady St. Mary’s church is a large and very ancient edifice, and belonged to the priory. The value of the living is not returned in the Reports of the Ecclesiastical Commissioners. The parish is in the diocese of Bristol.
Wareham is said to be a borough by prescription, but this is doubtful. Hutchins, the historian of Dorsetshire, states that there was a mayor of Wareham in the reign of Richard II. In the reign of Queen Elizabeth a charter was granted, constituting Wareham a borough. A charter was granted in the reign of Queen Anne, which defined the constitution of the municipal body as consisting of a mayor, burgesses, and assistants burgesses. The borough Court of Record has fallen into abeyance since 1766. The boundary of the municipal borough comprises portions of the three parishes beyond the town and these parts are denominated the out-parishes. The town is not affected by 5 & 6 Wm. IV. c. 76, for the reform of municipal boroughs, and was therefore not to be called a borough from the reign of Edward I. to the passing of the Reform Act, under which it now returns one member: the adjacent borough of Corfe Castle, which returned two members, was disfranchised. The parliamentary borough now comprises both the in-parish parishes, and part of the chappelry of Arne in Trinity parish; the parishes of Corfe Castle and Bere, and parts of the parishes of East Stoke and East Morden. The population in 1831 was 3774, including 1703 for the old borough. The number of electors on the register in 1835-6 was 572, and 428 in 1839-40.

The neighbourhood of Wareham is flat and marshy, but the town is situated on an eminence between the rivers Frome and Piddle, over which there are bridges, one having five arches. The only method of warehousing at one end of town—quay from the sea, and those of 60 tons can approach within half a mile; three miles from the town, at the confluence of the Piddle and Frome, vessels of the largest size can anchor. Wareham is a member of the port of Poole. The principal soil is a mixture of clay found in the parish of Corfe Castle and in the neighbourhood, which is in demand for the manufacture of common earthenware in Staffordshire. The market-day is the Tuesday, and there are fairs for cattle, cheese, and hogs, in April, May, and September. A Rye southwest, a cattle-fair in the spring. The town is compactly built, with two wide main streets lying at right angles, and several smaller streets. In 1834 it was neither lighted nor watched. There are two public houses, one of warehouses, and one of corn. In 1833 there had been withheld for two or three years, according to the 'Education Returns' of 1833.

(Reports of Corporation Commissioners, Boundary Commissioners, &c.)

The system of warehousing is a custom's regulation, by which articles of import may be lodged in public warehouses at a moderate rent, not being chargeable with duty until they are taken out for home consumption, and being exempt from duty if re-exported. It affords valuable protection to the merchants and traders of Great Britain, particularly to the public revenue. Where no such system exists, the merchant must either pay the duty on every article immediately it is landed, or must enter into a bond with sureties payable at a future time. If he pays on arrival, he is liable to lose a large cargo, on which interest must be charged to the consumer until the goods be sold; or he must effect an immediate sale, perhaps at an inadequate price, or even at a loss, in order to raise the funds necessary to pay the duty. If he wishes to defer the payment until the market shall offer an advantageous sale, he may find it difficult to induce persons to become his sureties, and, when he has succeeded, he may involve them in ruin. The natural result of these difficulties is, that the re-exportation of articles of commerce, on which heavy duties are charged, and a monopoly is thus established, to the great injury of the consumer. The immediate payment of customs' duties also obstructs the carrying trade of a country, by making the re-exportation of articles of commerce, as well as expediting their arrival, very expensive. The first British statesman who proposed a remedy for these evils was Sir Robert Walpole, in his celebrated Excise scheme, in 1723. His object was to unite the Excise laws with those of the Custom House, and thereby obtain a small duty immediately on importation, and the remainder on being removed from the Excise warehouses for home consumption. Speaking of tobacco, he thus explained his proposal:—'If the merchant's market was consulted, it would be very easy to apply to the keeper, and take out as much for that purpose as he has occasion for, which, when weighed at the custom-house, shall be discharged of the three farthings per pound with which it was charged upon importation; so that the merchant may then export it without any further trouble. But if its market be for home consumption, that he shall then pay the three farthings charged upon it at the custom-house upon importation; and that then, upon calling on his warehouse-keeper, he may deliver it to the buyer, on paying an inland duty of 4d. per pound to the proper officer appointed to receive the same.' Walpole clearly foresaw the advantages of his scheme in 1723:—'I am certain,' he said, 'that it will be of great benefit to the revenue, and will tend to make London a free port, and, by consequence, the market of the world.' This wise plan, unfortunately for English commerce, was not permitted to be tried. [Weekly Register, July 1723.]

The advantages of the warehousing system were most forcibly pointed out by Dean Tucker in 1748, in his 'Essay on the Advantages and Disadvantages which respectively attend Great Britain and France with respect to Trade,' and afterwards by Adam Smith, in his 'Wealth of Nations,' but it was not established before 1803 (43 Geo. III., c. 132). The Acts by which warehousing is now regulated are the 3 and 4 Will. IV., c. 57; 4 and 5 Will. IV., c. 69; and 6 and 7 Will. IV., c. 136. The commissioners of the treasury are empowered to determine the ports at which goods may be warehoused, and the warehouses in which particular descriptions of merchandise may be deposited. The various regulations and restrictions under which warehousing is carried on, and the conditions under which the privilege is extended, are fully explained in Ellis's 'Customs, Laws, and Regulations,' vol. ii., pp. 240-377, edition 1841; and 'Yearly Journal of Trade,' for 1843, by Charles Pope, pp. 396-404.

Sir Robert Walpole's scheme was that the warehousing was compulsory, but, under the existing law, it is at the option of the importer. Amongst other privileges enjoyed by the merchant, he may remove the merchandise from one port to another, either by sea or inland carriage, to the end, and it is said to have sustained little or no loss in these removals, and it naturally becomes a question, Why should warehousing be confined to sea-port? It is obvious that the main object is to preserve the convenience to the merchants and traders of inland towns, and no reason can be assigned for not conceding it, except insecurity to the revenue. But if goods may be removed with safety from London to Hull, they could be removed from London to Brighton, or from Hull to York. Government would incur no expense in erecting warehouses, as they would be provided by private capitalists, in the same manner as the docks and warehouses in London, Liverpool, and the like. None of Commons reported in 1840, that the privilege of having bonding warehouses may be conceded to inland towns, under due restrictions and regulations, with advantage to trade and safety to the revenue; and since that time, the scheme has been promoted for carrying the scheme into effect.

The advantages of warehousing have been understood in various foreign countries as well as in England. So long since 1804, M. Turgot established it in France; but it was discontinued in 1809, except for merchandise imported from the East and West Indies and Guiana, or exported thereto. In 1805 the system was re-established in a more extensive manner, but was confined to certain sea-ports, until 1832, when it was extended to the interior. Warehousing both at the ports and at certain inland towns is permitted in Holland. In Belgium, Denmark, and other commercial countries the system has also been adopted. It has recently been proposed for adoption in the United States of America, and recommended not only on account of its importance to trade, but for a novel reason—its republican tendency. The President, in his message of December 1842, said that, without such a system of warehousing, the merchant capitalist, and therefore every man at home, would possess, after a short time, an almost exclusive monopoly of the import trade, and laws designed for the benefit of export thus operate for the benefit of the few. Similar systems have sprung up in all its tendencies.

WARGENTIN, PETER WILLIAM, a Swedish astronomer, was born at Stockholm on January 22, 1717. When he was only twelve years of age.
occurred a total eclipse of the moon, and the observance of this phenomenon is said to have inspired him with a taste for the sciences, which was cultivated by Dr. Leibnitz, and which was improved by his association with Klingenstierna and Celsius, by whom he was recommended to study the motions of Jupiter's satellites; and in 1741, on taking his degree of master in arts, he made a tour to Italy on the subject of those motions. Wargentin spent, in fact, the greater part of his life in efforts to correct the theory of the satellites; and, confining himself almost wholly to this branch of the science, the improvements which he made in it obtained for him the title of the first of the German astronomers.

On the death of Celsius, in 1744, he was chosen corresponding member of the Academie de Paris, and five years afterwards he succeeded Elivius as perpetual secretary of the Academy of Stockholm. In 1759 he was made a knight of the Polar Star, and in 1760 he was elected a fellow of the Royal Society of London. He was also a member of the academies of St. Petersburg, Göttingen, Copenhagen, Drontheim, &c., and his communications to these societies are very numerous. When he was a candidate for the professorship at Upsal, he delivered a discourse on the progress of astronomy since the commencement of the century; and in the 'Memoirs of the Academy of Stockholm' there are several papers by him on the population of Sweden.

It was during the American War that he wrote dissertations on the transits of Venus which took place in 1761 and 1769.

In order to determine the parallax of the moon, Wargentin made, at Stockholm, observations on that luminary simultaneously with the corresponding observations which were made by Dr. Bradley at Greenwich. Good House is, from a formal agreement made between the two astronomers previously to the voyage of the latter to the southern hemisphere; and from the observations so made the value of the parallax was correctly ascertained.

Wargentin married in 1750, and became the father of six children, three of whom survived him. He died December 13, 1783, leaving the reputation of having been a man of amiable manners and disinterested character. His decision of science interested his posterity in attention to a private affair, and it is said that, near the close of his life, he was in part indebted to his friends for the means of being extricated from some embarrassments into which he had fallen. The Academy aided him from its funds, and struck a medal with an inscription denoting its sense of his merit. It also procured for his family a pension from the government.

An interval of time in which the inequalities of the two first satellites of Jupiter are compensated, had been noticed in 1714 by Dr. Bradley, who observed it during use of the period; and Wargentin, apparently without any knowledge of Bradley's discovery, both found the values of the inequalities and the time of the compensation. With respect to the first satellite, the celestial astronomer introduced the constant of the equation, and an equation amounting to 3° 40', which he subsequently reduced to 3° 39', and whose period he found to be 437 da. 19 ho. 41 min.; and, with respect to the second, he introduced an equation amounting to 16° 30', whose period is also about 437 days; these empirical equations have been confirmed by the researchers of La Place, who have found that they constitute in reality two equations of the centre for those satellites. Wargentin also rectified the equation of Jupiter respecting the aberration of light, and that which depends on the eccentricity of Jupiter's orbit. His first tables of the movements of the satellites were published in the 'Acta Societatis Regni Upsaliensis, ad an. 1741,' and an improved edition was published by La Place in 1768. His tables of the comets and those of Halley and Flamsteed were collated by the late Mr. Colton, and the former one was found to be much more correct, and thus they became of great importance by affording the means of determining the longitudes of stations.

It is to be remarked that these tables were formed without the use of physical astronomical observations, which determined the motions of the satellites from a combination of all the observations of their eclipses which he could procure, and during the whole of his life he laboured to correct the errors which he discovered. He sent new tables of the third satellite to Dr. Makselye, who pub-

lished them in the 'Nautical Almanac' for 1771; and the Almanac for 1779 contains an improved edition of the tables of the second satellite.

WARHAM, WILLIAM, an eminent English prelate, was born at Okeley in Hampshire, in the latter part of the fifteenth century, and after receiving his school education at Winchester, he entered the University of Oxford, in 1470. Here he remained, having in due time taken his degree of L.L.D., till 1488, when he is understood to have been collated to some living in the church. Soon after however he is found to be practising as an advocate in London, and in 1489 practised as one of the Principal or Moderator of the Civil Law School in the parish of St. Edward's, Oxford. His first public employment, as far as is known, was the mission upon which he was sent, along with Sir Edward Poyninges, by Henry VII., in 1483, to Philip, Duke of Burgundy, to persuade him to exercise his influence to put an end to the support and encouragement given to Perkin Warbeck by Margaret duchess-dowager of Burgundy. Bacon, who, in his 'History of King Henry VII., gives a speech addressed upon this occasion to the Duke, which is called Sir William Warham, doctor of the canon law. Although his endeavours in this affair were attended with little or no success, he continued to rise in the good opinion of Henry, and was appointed to a number of important offices of state; and he was made master of the rolls this same year, keeper of the great seal in 1502, and lord chancellor on the 1st of January, 1503. In 1503 he was also made Bishop of London; and in 1504 he attained the summit of his career by being raised to the archbishopric of Canterbury.

Warham opposed the marriage of Catherine, the widow of Prince Arthur, with his brother Henry, both when it was first proposed in the time of Henry VII., and afterwards when it was carried on by Henry VIII. for the sake of the next reign. This brought him into collision with Fox, bishop of Winchester, whose rivalry and hostility were afterwards inherited by his protégé the famous Wolsey. This latter, now become the chief favourite of Henry VIII., was substituted for Warham as chancellor in 1510. Before and after this, there were many contests as to jurisdiction between the archbishop and the cardinal; but Warham lived to see the fall of Wolsey, and even upon that event, in 1529, to have the great seal again offered to him, although his advanced years induced him to decline it. He died at St. Stephens, near Canterbury, 23rd August, 1532, leaving the primacy open to the new faith and new politics of Cranmer.

The biographical sketch of Warham is drawn as follows, not perhaps without some natural party prejudice, by Burnet: 'He was a great canonist, an able statesman, a dexterous courtier, and a favourer of learned men. He always hated Cardinal Wolsey, and would never stoop to him, esteeming it below his dignity to humble himself before him. He was a zealous advocate to the learning of the schools as others were, but set up and encouraged a more generous way of knowledge; yet he was a severe persecutor of those whom he thought heretics, and inclined to believe fanatical people.' This last remark is founded on the part the archbishop took in the affairs of the Maid of Kent, to whose impostures, either from credulity or party spirit, he showed some inclination to listen.

Warham was a great friend and patron of Erasmus, who dedicated to him his edition of St. Jerome, and in his letters speaks in the highest terms both of the learning and abilities and of the virtues of the archbishop.

WARING, EDWARD, the son of a wealthy farmer who traded in fish, and was the principal owner of a manor at an early age a decided taste for geometry and algebra, he was sent, in 1733, to Magdalene College, Cambridge, where he made great progress in mathematical analysis. He attained the rank of senior wrangler, and took the degree of B.A. in 1737, when he turned one of the chairs of the Lucasian professorship of mathematics being vacant by the death of Mr. Colton, Waring became a candidate for, and succeeded in obtaining, that honourable post; he was also appointed by Wren a fellow of Corpus Christi College, and having, in order that he might prove himself to be qualified, published a portion of a mathematical work which he had commenced, a war of pamphlets on the subject of the work was, before the election, carried on between the two rival candidates and their friends. Waring not

67

having taken the degree which was required by the statutes, a licence from the crown was obtained for the purpose of enabling him to hold the appointment.

In 1763, being the tenth year of his age, Mr. Waring was elected a Fellow of the Royal Society; and in several of the volumes of the 'Philosophical Transactions' there appear papers by him on subjects connected with the theory of equations, centripetal forces, &c. In the volume for 1779 is an account of his theory of light, which, when from an open fire is radiated from the burning fuel, instead of being conducted by the air, this heat, diminishing in intensity as the square of the distance increases, is very unequal, being too great at a small distance, and too weak at a greater; while when directed, or 'drest,' or 'drawn,' as the chimneys of houses are called, which feeds the fire with oxygen, acts like a chilling blast against the side of each person or object which is turned away from the fire. 

Strata of air unequally heated.—Be- 

cause of this, there arises from this circumstance—that the equatorial current, being colder and specifically heavier than the air previously in the room, occupies the lowest stratum, and subjects the feet to a 'cold bath,' which is frequently attended with bad consequences. Other objections are—the smoke and dirt arising from the use of open fires; the loss of time attendant on the care which they demand; the danger to property and to person which accrues from them; the necessity (until lately supposed to be indispensable) of employing climbing-boys; and many others.

Many contrivances have from time to time been brought forward to obviate one or other of these inconveniences. Count Rumford suggested the 'regular stove,' the peculiarity of which consists in narrowing the entrance or throat of the chimney, and placing a plate or grate so as to vary the size of the aperture; by this means, particularly if the opening be near the fire, the very hot air directly from the fire enters before it can mix with much colder air; this prevents the draught from being so strong as to lessen the chance of smoking. But the very circumstance which constitutes the excellence of this stove, viz. the rapid ascent of heated air up the chimney, illustrates the waste of the method generally by showing how much of the heating agent is lost. The almost infinite variety of open fire-places, both in the form of the grate itself and in that of the opening in which it is placed, have been introduced either for an ornamental purpose or for the prevention of smoking; for the other evils enumerated are more or less removable, the current of air through the stove, the new of air, and the suddenness of the currents which blow. These defects have led to the more extended use of Close Stoves.—The common Dutch stove is one of the simplest examples of a close stove. It generally consists of a cylindrical case of sheet iron, within which a hole of which is a grate for containing the fuel. There is an ash-pit beneath the grate, and three openings to the interior—one to the ash-pit, one for introducing the fuel above, and one leading to a flue or chimney. When the fuel-doors are closed and the door opened, each is then one aperture by which cold air can enter to feed the combustion, and another by which the smoke can escape. In this form of stove the heated iron core warms the air of the room by conduction rather than radiation, heated air remaining in the stove and raising the temperature of the room by convection, while cold air is heated in the flue or chimney. There is also great economy of fuel, and an absence of smoke and dust. On the other hand an inconvenience arises from the highly heated iron, the temperature of which is so great as to decompose—not the air itself, as is sometimes, but erroneously stated—but many of the heterogeneous particles always floating in the air. The air acquires a burnt and sulphurous odour; it exercises a dry and shrivelling effect on objects in the room, and often produces headache and giddiness to those who are exposed to it. In Germany the stoves are made on this principle, but are more ornamental in their character.

The Russians contrive their close stoves on a different plan, and brickwork is largely used. Instead of metal, as a means of making the heat less intense near the stove, and of keeping up a reservoir of heat after the fire is extinguished. The stove is built in an ornamental style, and consists of a box of which the lowest serves as the fire-place, and the upper ones as flues; and being composed almost entirely of brick and porcelain, the outer surface remains at a moderate temperature for a very long period.

A recent German stove, white or semi-white, is a more effective kind of fires in Russia, says—Wag great houses not a breath of cold is experienced. The rooms are heated by stoves, frequency and otherwise; being built in lower storey. 

...
over story, of pure white porcelain, in various graceful architectural mouldings; sometimes surmounted with classic figures or groups, openings, or with brass doors kept as bright as if they were of gold. In houses of less display, these stoves are merely a projection in the wall, coloured and crowded in the same style as the apartment. In adjoining rooms they are generally placed back to back, so that the same fire suffices for both. These are heated but once in the twenty-four hours, by an old Calibran, whose business during the winter it is to do little else. Each stove will hold a heavy armful of billet, which blazes, and is heated most meretriciously, when the ashes have been carefully turned and raked with what is termed an "open-gavel," or stove-fork, so that no unburnt morsels remains, the chimney aperture is closed over the glowing embers, the brass doors firmly shut, and the fire is in about six minutes in the hole. It is at the bottom indeed it never cools.

Modern English Close Stoves.—Within the last few years many forms of stove have been devised, with the view of obviating some of the objections urged against those used on the Continent. Where, as in a common German or Dutch stove, the burning fuel comes in contact with the metal of which the stove is formed, this metal becomes so highly heated as to produce upon the surrounding air the deleterious effects before alluded to. Dr. Arnot of Edinburgh first brought this subject to the attention in a particular manner to this subject. Having devised a new form of stove, he fully described it in a work published in 1838; but before publishing the book, he detailed the nature of the apparatus in a letter before the Royal Society, stating that, to use his own words, "as I had decided not to reserve for myself any patent right in the new apparatus, I might, by having numerous competent witnesses of what I had proposed and accomplished, prevent any misapprehension of my proceedings in appropriating them by patents, and thus coming between me and the public." The problem which Dr. Arnot sought to solve was, to obtain a considerable extent of surface heated not much above 200°, as a means of WARNING and POISON. The first cause of a large amount of heat was to be constructed, having a fire-box in its centre; and by certain arrangements for the admission of air and the emission of smoke, he kept the water always nearly at the boiling temperature. This apparatus being both expensive and difficult to manage, he disposed of the water, and surrounded the fire merely with a body of air. In the new form of stove, the fuel is put into a small fire-box, enclosed within a larger case of sheet-iron, the only opening of which is the case itself. Above, at which point the pipe is introduced, an air-hole beneath the grate, and a chimney for the exit of smoke, which chimney, being merely a metallic tube three or four inches in diameter, can be easily arranged in position. The interior of the outer case is divided into two parts by a partition so adjusted as to cause a continued circulation of the heated air within, and hence an equable heating of the outer case. The air vent leading to the fire is provided with a valve, by which the admission of air is rendered more or less abundant according as the fire is, or is less or more intense. It was one point in Dr. Arnot's system to make the stove a 'self-regulating' one, by providing apparatus whereby the valve would open and shut at the proper times to maintain any required temperature; and it suggests six or eight different modes of arrangement, from which the architect and the stove may each select. Dr. A. states: 'During the winter 1836-7, which was very long and severe, my library was warmed by the thermometer-stove alone. The air received no fresh air, and was lower or higher in temperature than the room by the amount of heat only.' The Chinese have been before us in this matter.

Warming by Heated Air.—In the arrangements yet described, the stove or fire-place is the element which is to be warmed, and its heating effects are calculated with respect to that room alone. A notable advance, carried to a great extent in the present day, is to have the fire in an outer or lower apartment, and to vary the heated air to suit the circumstances. As the provisions of the Chinese have been before us in this matter. In the better class of Chinese houses there hollow fluxes extending beneath the floors, and connected with a space constructed either against the exterior walls of the place to be heated, or else in an interior room adjoining. The fluxes are perforated with numerous holes, through which they give out the heated air and smoke to the whole of the under side of the flooring. This flooring consists of flat tiles or flag-stones nicely indebted to a prevention of the smoke or heated air from the fluxes beneath into the room. After circulating beneath the tiled floor, the smoke escapes by a chimney into the open air. In this arrangement, it is obvious, the apartment except for exposure to the heat from the warmed tiled floor to the air of the room; and as this conduction proceeds slowly, the tiles retain heat enough to warm the room hours after the fire has been extinguished.

Before the linked methods of warming factories came into use, Mr. Sritt, of Derby, devised a form of stove which, under various modifications, was called the 'cock-stove,' the 'Derby stove,' and the 'Helping stove,' forming his cotton-factories. In these stoves the flue was contained in an iron box, sometimes cylindrical, sometimes rectangularly; and at a certain distance from it, encompassing it on every side, was a thick casing or envelope, so that a body of air existed between it and the fire-box. The fire-box had three openings to the exterior, one to introduce the fuel, one for an ash-
and air-vent, and one for a chimney; the exterior envelope too had two openings, wholly distinct from the ones, to carry off heated air to the various rooms of the factory, and another to admit a renewed supply of fresh air. This form of stove under various modifications has been extensively employed, but it is now probably nearly superseded.

Dr. Tredgold describes an arrangement adopted in a church, which may perhaps be taken as a fair example of a numerous class of instances. The length of the body of the church is about sixty feet, and the breadth forty-five. This is warmed by two stoves about four feet high, made of cast-iron, fixed at either end of the church, and the smoke is led out of room, for the entrance of fresh air to the air-chamber, and for the exit of the heated air to perform its wonted office. The air-tubes, communicating with the air-chamber of the stove, are conveyed along the lower edge of the gallery of the church; and small branch pipes opening from them at regular intervals give out a stream of hot air which mingles with the cold air of the building. The fires are lighted about four or five o'clock on the Sunday morning, and the heat is left to the use of the occupant of the church as the season advances it is usual to light them earlier. From this time till the congregation assembles the fires are constantly supplied with fuel, and a supply of heat is thus kept up sufficient to warm the whole interior of the church during the time of divine service.

A stove such as the one just described is as likely to give a tainted and offensive character to the air as the common German stoves, unless a rapid current be kept up. Hence a change has been occasionally introduced, by having the outer casing and the air-chamber of Mr. Scott Russell, and to that end, making its dimensions much larger, an arrangement which heats the outer case less intensely, and provides a larger body of air heated to a lower temperature.

Warming by Steam.—The employment of steam-boilers in large factories, and the adoption by Sir W. Tredgold of the steam-heating apparatus, is one of the circumstances which have led to the very extensive adoption of the method of warming by steam. A marked difference is observable in the principle of this method, as compared with that of hot-air warming. The heated agent, i.e. the steam, is not permitted to mix with the air of the room which is to be warmed, but acts through the medium of the metallic tube which confines it, and which it raises to a temperature sufficient to warm the room; the air is then burnt without being mixed with the air.

The general arrangements of a steam-heating apparatus, as suggested by Mr. Scott Russell, are somewhat as follows: At a convenient part of the building, and as low as possible, there is to be placed a close steam-boiler of the ordinary kind, and having a large space attached to it, ready to be carried to the part of the building which is to be warmed. This small pipe should be pretty thick, and carefully rolled round with a bandage of flannel to the thickness of a quarter of an inch, and the boiler should be wholly covered with bricks and plastered over to keep in the heat. This smaller steam-pipe should have an area of one square inch for every six gallons of water that the boiler can boil off in an hour. Pipes of a larger size are to be laid round the sides of the building in such a manner as to allow a free circulation of warmed air to enter the room. Into these larger pipes the steam is to be conducted, and in them the steam will be condensed into water, giving out its heat to the colder air of the room which is in contact with it. The condensation in the pipes must be provided for, the purpose of bringing back this condensed water into the boiler, for which movement a gentle siphon is given to the pipes. The water thus returned, being again heated in the boiler and converted into steam, is conducted to the various parts of the building and give out its caloric to the room which is to be warmed.

The efficacy of this mode of heating depends on the great capacity for heat which steam possesses, a capacity equal to 1000° of Fahrenheit, or nearly 1200° of Centigrade, degrees of heat in becoming a pound of steam. Steam will thus communicate as much heat as a mass of red-hot iron; and it will have this advantage over the iron, that it can carry this heat a distance without a similar loss, because the heat, being latent, will not be given out until it arrive at its destination and become condensed, when the whole of its 1000° will be usefully applied.

The quantity of steam or pipe thus required. Dr. Arnott, after taking account the loss of heat through the thin glass of windows, the thick walls of buildings, and through various openings and crevices, arrives at the following result: — In a winter day, with the external temperature at 10° below freezing, to maintain in an ordinary apartment the agreeable and healthful temperature of 65°, there must be a quantity of steam per hour, that is about a foot high, rests on four balls, and supports a fire-box or furnace. Concentric with this fire-place is an outer case; the space between the two containing the air which is to be warmed. The usual adjustments are provided for the introduction of fuel and of air-vent to it, for the exit of smoke, for the entrance of fresh air to the air-chamber, and for the exit of the heated air to perform its wonted office. The air-tubes, communicating with the air-chamber of the stove, are conveyed along the lower edge of the gallery of the church; and small branch pipes opening from them at regular intervals give out a stream of hot air which mingles with the cold air of the building. The fires are lighted about four or five o'clock on the Sunday morning, and the heat is left to the use of the occupant of the church as the season advances it is usual to light them earlier. From this time till the congregation assembles the fires are constantly supplied with fuel, and a supply of heat is thus kept up sufficient to warm the whole interior of the church during the time of divine service.

A stove such as the one just described is as likely to give a tainted and offensive character to the air as the common German stoves, unless a rapid current be kept up. Hence a change has been occasionally introduced, by having the outer casing and the air-chamber of Mr. Scott Russell, and to that end, making its dimensions much larger, an arrangement which heats the outer case less intensely, and provides a larger body of air heated to a lower temperature.

Warming by Steam.—The employment of steam-boilers in large factories, and the adoption by Sir W. Tredgold of the steam-heating apparatus, is one of the circumstances which have led to the very extensive adoption of the method of warming by steam. A marked difference is observable in the principle of this method, as compared with that of hot-air warming. The heated agent, i.e. the steam, is not permitted to mix with the air of the room which is to be warmed, but acts through the medium of the metallic tube which confines it, and which it raises to a temperature sufficient to warm the room; the air is then burnt without being mixed with the air.

The general arrangements of a steam-heating apparatus, as suggested by Mr. Scott Russell, are somewhat as follows: At a convenient part of the building, and as low as possible, there is to be placed a close steam-boiler of the ordinary kind, and having a large space attached to it, ready to be carried to the part of the building which is to be warmed. This small pipe should be pretty thick, and carefully rolled round with a bandage of flannel to the thickness of a quarter of an inch, and the boiler should be wholly covered with bricks and plastered over to keep in the heat. This smaller steam-pipe should have an area of one square inch for every six gallons of water that the boiler can boil off in an hour. Pipes of a larger size are to be laid round the sides of the building in such a manner as to allow a free circulation of warmed air to enter the room. Into these larger pipes the steam is to be conducted, and in them the steam will be condensed into water, giving out its heat to the colder air of the room which is in contact with it. The condensation in the pipes must be provided for, the purpose of bringing back this condensed water into the boiler, for which movement a gentle siphon is given to the pipes. The water thus returned, being again heated in the boiler and converted into steam, is conducted to the various parts of the building and give out its caloric to the room which is to be warmed.

The efficacy of this mode of heating depends on the great capacity for heat which steam possesses, a capacity equal to 1000° of Fahrenheit, or nearly 1200° of Centigrade, degrees of heat in becoming a pound of steam. Steam will thus communicate as much heat as a mass of red-hot iron; and it will have this advantage over the iron, that it can carry this heat a distance without a similar loss, because the heat, being latent, will not be given out until it arrive at its destination and become condensed, when the whole of its 1000° will be usefully applied.

Dr. Tredgold wrote his treatise on 'Warming and Ventilating' about twenty years ago, employing the method of warming by hot air most extensively adopted; and he accordingly directed the chief part of his attention to the exposition of the principles on which that method rests. But the 'hot-water' method has been so far improved by the experience of the past few years, that at the present day be deemed the favourite one for public buildings, halls, and large apartments where steam-boilers have not been previously employed for other purposes.

The principle on which the hot-water method is founded.
WAR

is different from all the others which have passed under our notice. When a vessel of water is heated, the water does not become hot by the conduction of caloric from particle to particle, but from the ascent of heated particles from the bottom, where we suppose the heating agent to be applied, to the upper strata. This is proved from the circumstance that if heat be applied only to the surface of the water in a vessel, it is by extremely slow degree that the colder particles at the surface descend to supply their place; and hence a series of ascending and descending currents ensues. If, instead of leaving the heated water only in a vessel, it ramify also through closed tubes connected with the vessel, the ascending and descending currents may be passed through different parts of a building, and from the room where the vessel itself may be placed.

The heat, rising, to 212°, or to any temperature depending on the fire to which it is exposed, gives out heat to the metallic pipe through which it passes, and this pipe again communicates heat to the air of the room. Hence the operation of this method of warming depends on the circulating, or ascensive and descensive property of heated water, by which the portions of pipe furthest removed from the fire become as much heated as those in its immediate vicinity.

Vessels provided to be warmed are on one level, an open boiler may be used; but where it is necessary to carry the pipes to different floors of a building, some of them much above the level of the boiler, the building must be constructed with closed tubes. Whatever kind of boiler is employed, a pipe branches out from the upper part of the side, extends horizontally through the rooms to be warmed (without in any case rising above the level of the water in the boiler), and returns again to the boiler, which it enters at a lower level than the other. Under this arrangement a current of heated water will flow from the boiler at the upper orifice, and, after traversing the tube, return to the lower orifice.

The closed boiler is however more extensively useful, air varies its temperature of 40°, or 5 cubic feet of fresh air per minute for each individual in a room artificially lighted, of course involves the condition that an equal quantity of vitiating air per minute must be allowed to escape, and, the inquiry naturally follows—How long will a cubic foot of fresh air occupy in escaping through an orifice of a certain size? Carbonic acid gas is heavier than atmospheric air; but there are three circumstances which render required air rather lighter than the general air of a room, viz., the existence in it of nitrogen and vapour, both of less specific gravity than the air, and the vitiating air which escapes from the air of the room. From these circumstances combined, it is found that required air ascends to the upper part of the room; and it follows that the ceiling or some neighbouring part is the proper place for an outlet.

Practice of Ventilation.—In nineteen-twentieths of all the buildings constructed, there is no account whatever taken of the means for insuring ventilation. The fire-
are constructed, the windows fixed, and the doors hung without a thought being paid to the means of effecting a communication between the air contained within the apartments. But it is probable that in most English rooms, provided they are with tolerably large open fire-places, and with doors which are frequently opened, the ventilation is sufficiently complete. The fresh air enters the room by the open window or door, and that has been shown sufficient to prevent much, if any, ventilation, which may exist at a small height from the floor; while the vitiated and specifically lighter air escapes partly up the open fire-place and chimney, partly near the upper extremity of the open doors, and partly by crevices around doors and windows.

In crowded rooms however, where the amount of vitiated breath bears a much larger ratio to the cubical contents, and where the doors are generally small compared with the height of the room, the impure air cannot escape by these means, and some arrangements must be made near the ceiling for the removal of the air. These methods are chiefly of two different kinds, the one by the use of a revolving wheel or fan, and the other by the action of a chimney.

We sometimes see one of the upper panes of glass removed from a window, and its place supplied by a revolving fan, as a means of ventilating the apartment. This fan or wheel is provided with null formed like the sails of a wind-sail, or the blades of a screen-propeller, so that any force which sets the wheel in motion will cause a current of air to pass obliquely between them. But in this case the fan is made to revolve merely by the impulse of the air itself, and is not under the control of the inmates of a building, the latter complete opening doors and air-passages by the arrangement of the large cotton-mills of the North.

The observation has been correctly made, that the first accomplishment of perfect ventilation for a crowded place was not, as might have been anticipated, in the houses of the great and learned, and therefore in our houses of parliament, or in the churches of the wealthy, or in fashionable assemblies of any kind, but in the cotton-factories.

The same cause, which goes far to explain the general adoption of steam-warming in factories, will probably be available for the wider diffusion of ventilating apparatus, while the boilers of a steam-engine furnish the requisite steam in the one case, the power engendered is applicable to the fan in the other.

A fan or wheel, fan-ventilator, or wind-fan (for by all these names the contrivance is known), being placed in any convenient position, is set in motion by the steam-engine of a factory, and by its rotation discharged the vitiated air from a series of rooms with great rapidity. Dr. Ure ('Philosophy of Manufactory') gives the following description of one variety of wind-fan used in the factories. It consists of two cast-iron end-plates, A A, having a central circular opening, c c c, from the circumference of which the outline of each plate enlarges spirally, the point nearest the centre being A A, and that nearest the end of the fan being B B (Fig. 1). These two parallel plates are connected by bolts, a a a; a mantle of sheet-iron being previously inserted into grooves cast in the edges of the end-plates so as to enclose a cavity with an elongated outlet at B, to which a pipe is attached for carrying off the wasted air in any direction. Within this cavity a shaft C revolves, in bearings b b, placed centrally in the frame-plates A A, and cast in the same piece. On this shaft a boss is wedged fast, bearing five flat arms, c c c, to which are riveted five flat plates, or, wires, of the shape shown between a and a (Fig. 2), having a semi-circular piece cut out from them each side, about the size of the end openings. On one end of the shaft C, beyond the box-bearing, the loose and fast pulleys D are fitted for receiving the driving-band, and for turning the wings in the direction shown by the arrow. Thus the air is driven before them B B, and emerges from the five openings at c c c (Fig. 1). By the centrifugal force of the revolving wings, the air is condensed towards their extremities, and makes its escape from the pressure through the orifice B, while it is continually drawn in at the sides by its tendency to restore the equilibrium. Dr. Ure says that 'when such a fan, placed at the one end of an apartment about two hundred feet long, is in full action, it throws the air so powerfully out of it as to create a draught at the other end of the apartment, capable of keeping a weightted door shut at will.'

An account was given in the London Journal of Arts, 1842, of the method adopted in warming and ventilating the Reform Club-house, which illustrates our present subject. A steam-engine works a revolving fan, capable of throwing ten thousand cubic feet of air per minute through a subterranean tunnel under the basement story; and the steam of condensation, from the small steam-engine which works the fan, supplies three cast-iron chutes with the requisite heat within the building.

The second mode of effecting ventilation, viz. by the use of a tube or chimney opening into the air from the upper part of an apartment, depends for its action on the ascending power possessed by a lofty aerial column. As a draught-actuated chimney will elevate the air in the room, it follows that if the chimney is made to carry off impure air more rapidly than a low room, and in many of our public buildings this arrangement is deemed sufficient. In the Reading-room at the British Museum, for example, the arrangement of the openings of the windows has been vitiated, independent of the operation of doors and windows, are these:—A current of cool air sets in from the stone vaults or passages beneath, through a hole or holes in the floor of the room, and in the lateral ventilation, from whence it finds entrance into the room through the eight coil-tube pedestals. If the weather be cold, and the pipes be filled with hot water, the air, passing thus around and between the pipes, becomes warmed, and enters the room at a temperature sufficient to warm the whole contents; but if the weather be warm, and the pipes contain no hot water, the air passes by the pipes without being affected by them, and enters the room at its natural temperature. The air, after being vitiated by a draught, carries along with it vitiated air, and escapes through circular ornaments in the ceiling into a horizontal tube between the room and the apartments above, and finally escapes into the open air.

The temporary House of Commons is an example of ventilation by a beneficent draught caused by a lofty chimney. By the side of the building has been constructed a large circular chimney, 120 feet high, 11 feet wide at the bottom, and 8 feet at the top, with a fire-plate near the bottom having 25 square feet of bars or surface. This chimney is connected, by a tunnel leading from its base, with the interior of the house, and is intended solely to remove the air from the house. Beneath the air-chamber and in connection with the room containing the hot-water apparatus, the house is warmed by a heated wall through which fresh air enters from Old Palace Yard. Three sets of folding-doors are so arranged that the air thus admitted can be wholly or in part allowed to pass through the hot-water room, or kept wholly free from it, according to the season of the year; so that it may be employed to enter the body of the house at any required temperature. The air thus admitted, after passing through the air-chamber into the house, and becoming vitiated by respiration and combustion escapes through apertures in the ceiling into a receptacle above, where it might be made to discharge itself into the open air. But in order to render the ascent of the air certain at all times, the upper receptacle is connected by a descending, and with an upper and a large fire-box made in the chimney, the high column of heated and rarified air engenders such a powerful draught as to blow out the whole of the air from the body of the house. There were some parliamentary papers presented to the House of
WAR

As relation Venti-Piantte Accurate it' curious, and but Leslie natural vated queathed to sixty remark of compiler the thing of

Dr. Warner advocated, which is the patent to be kept down by. It has had also a great reputation for the cure of cancer, but, like all other vaunted remedies for the cure of this disease, it cannot be relied on.

This plant was introduced into Great Britain in 1750, but being difficult of cultivation, it is seldom seen. It may be propagated by dividing the roots in spring or by sowing the seed, and must always be grown in a moist shady situation, as exposure to the sun will destroy it.

WARING, a mode of producing a deposition of the earthy matter which appears in rivers in which the current is frequently changed by the rising and falling of the tide. This causes a stirring of the water, which prevents the finer particles from being deposited. It is only necessary to produce a stagnation of the water for a few hours to have a certain deposit. Lead is commonly used for this purpose.

On the low flats which border the mouths of rivers, occasional inundations often cause a deposit which is highly fertilizing. Thus the polders in Holland and Friesland have been formed by the mud of large rivers, and, being dried and kept dry by dykes and shingles, have formed the most fertile soils.

Warping is an imitation of this natural process:—A bank of earth is raised along the course of the river, so high that the flood water, which has a more rapid course below this dyke is a sluice for the double purpose of letting the water and letting it out at pleasure. When the tide is setting in and counteracting the natural current of the river, the sluice is opened and the water flows in by one or more canals, the charge of water is raised by means of the lower lands, and covers it to the depth of high-water. The sluice is now shut, and the imprisoned water, becoming stagnant, deposits all the mud which it held suspended before. The sluice is opened at low-water, and the water is allowed to run out slowly, the mud or sediment, which hardens and dries rapidly. This operation is repeated until a thickness of several inches of new soil has thus been warped, when it is allowed to dry, and then ploughed and cultivated like any other field. It takes the same time to prepare any course of warped land as it first it looks barren mud; but it soon dries to a better texture, and ultimately produces very extraordinary crops. If its fertility decreases, and its surface is still below high-water mark, further measures will be taken. It is said that the Marshal Napier, in India, immediately restores the fertility. What is curious, is the almost total absence of organic matter in the warps, or rather, its intimate combination with the earth, so that it is not readily separated from them. It is neither like clay nor sand, but something between the two, soft to the touch, but not hardening into lumps when dry: neither very porous nor very retentive of moisture. The principal earth is silica in a very fine state. It generally contains a portion of calcareous matter, probably from comminuted shells. It has a whiter colour at the surface, it is easy to prepare, but it soon dries to a better texture, and ultimately produces very extraordinary crops.

The principal expense in warping is the sluice, and the channel through which the water is conducted over the land; the longer the water is kept above high-water mark, the better is the warping. The sluice is deposited in the channel, which has sometimes to be dug out. Accurate levels must be taken, or much expense may be incurred uselessly, if the water will not cover the land, otherwise it will not stick there.

It is of little consequence what the soil was originally; for a new soil is deposited over it. It should however not be too wet nor marshy: a porous soil is best, as this becomes the subsoil. All the inequalities which existed before are obliterated by the water, which fills up all cavities, and leaves a perfectly level surface. At an outlay of 2000l. a surface of 300 acres has been warped, increasing the value of the land more than 10,000l. in the course of four years—a very profitable speculation.
tuality of warped land naturally leads to the conclusion that silica, in a very comminated state, becomes best adapted for the roots of plants to shoot in and to supply them regularly with the moisture necessary to their vegetation, and that their chief nourishment is derived from the atmosphere, since very little organic matter can be detected in warp, and few mineral substances besides the earths.

**WARRANT.** A warrant is a delegation by A, who has power to arrest, to bring certain persons into effect, either to the custody of A, or to the custody of B. Thus a man having, of course, power to set in and manage his own concerns, may give a warrant of attorney to another to set or manage on his behalf. A sheriff who has power to arrest, &c., may give a warrant to his bailiff to arrest the objects of his jurisdiction. An officer of justice upon his warrant may give a warrant of distress to another for that purpose: A magistrate who has authority to bring before him persons who are within his jurisdiction, and who have committed certain offences, may make a warrant to others to do that act. A warrant, which should be in writing, ought to show the authority of the person who makes it, the act which is authorized to be done, the name or distinct description of the party authorized to execute it, and the party against whom it is made; and in criminal cases the grounds upon which it is made. The sense in which the word warrant is more generally known relates to criminal matters. A justice of the peace has power within his own jurisdiction to apprehend any person whom he has reason to believe is guilty of a trespass which he has jurisdiction. He may also verbally direct, that is, give a verbal warrant to others to arrest such person in his own presence. He may also give a warrant in writing to apprehend in his absence such person, or any person merely in the name of the justice of the peace, of which the instrument to the information of others. The warrant should always be under the hand and seal of the justice. It should be addressed to the constable or constables, or to some private person by name, and the constable or private person who has the warrant shall bear present in his own absence; and the justice's jurisdiction will not be liable for any of the consequences of obeying a proper warrant. The warrant shall name the person against whom it is directed. A warrant to apprehend all persons suspected, or to arrest any one person in general, is a danger of pointing out the individual person to be apprehended; it is vested in the justice, not in the officer. The law as to this was expressly laid down by Lord Mansfield in the case of Money v. Leach, 3 Bur. 1742, where the warrant, being of the form called a general warrant, and of which there had been in use since the Revolution down to that time, directing the officers to apprehend the 'authors, printers, and publishers' of the famous No. 43 of the 'North Briton,' was held to be illegal and void. The warrant should also set forth the time and place of making the commitment to be made. A warrant may be to bring the party before the justice granting it, or before any justice of the same county. A warrant of a justice of one county cannot be executed in another unless he is requested by the justice of that other county, and the same provision has been also enacted with respect to warrants granted in any one of the three kingdoms, and requiring to be executed in any other. But a warrant granted by one of the judges of the Court of Queen's Bench is tested in England, and may be executed in any part of the kingdom. A warrant is in force until it has been executed, if the justice granting it be still alive. An officer to whom it is addressed is indubitable if he neglects or refuses to act upon it; it is, in that event, a lawful and legal refusal of time, and in breaking open the doors of a house, but he ought first to make known to those within the cause of his coming, his authority, and to request their assistance. After the party is apprehended, the officer ought forthwith to present the warrant to the justice, and, if the justice be satisfied that the warrant is a legal one, he shall authorize the apprehension. Much of what has been said as to a warrant of apprehension is equally applicable to a Warrant of Commitment, which is the document by which a justice authorizes a commitment of a party to prison, pending a summary punishment or until his trial. The same matters are essential as to showing the authority, the parties, the cause, and the purpose of the warrant, and these latter should appear distinctly, be lawful, and not be in the disjunctive. A Summary is a document which authorizes a search to be made for stolen goods. (Burn's Justice.)

A Warrant of Attorney is an authority by which a man authorizes another to do an act for him, on his behalf, or as his agent or deputy. [Letter or Power of Attorney.]

But the term is most commonly applied to cases where a party executes an instrument of that name, authorizing or other to confound judgment against him in an action for a certain amount named in the warrant of attorney. It is generally given as a security by one who is, or is about to become, the debtor of another. The advantage of it is, that, by putting this power into effect, he prevents his debtor from selling his debtor at once, and has all the advantages of a judgment creditor, without the risk, delay, and expense of an action. There is frequently a condition attached, that it shall be defeased and become void upon the making or execution of payments, or other duties, demanded by the warrant; in such cases it is necessary that the defences, or condition, shall be written on the same paper or parchment as the warrant of attorney, and a copy of the whole filed in the Court of Queen's Bench within twenty days after the execution. Otherwise, in case of bankruptcy or insolvency of the party making the warrant of attorney, it will be void as against his assignees. If a warrant of attorney is more than one year old, and less than ten, leave must be obtained by a motion during term, or from a judge during vacation, to enter up judgment upon it; if ten years old or more, by a rule to show cause. Many other regulations and restrictions exist respecting the operation of this kind of instrument, but they are of too technical a nature to be here discussed.

**WARRANTY.** 1. The doctrine of warranty of lands was formerly one of the most important parts of legal learning, but the effect of warranties having been gradually reduced within very small compass, the subject has lost much of its importance, and those who would properly understand the English law of real property to pay some attention to this difficult subject.

Warranty existed in the civil law, and was defined to be the obligation of the seller to put a stop to the eviction and other troubles which the buyer may sustain in the property purchased. By eviction is meant the loss of either the whole or a part of the property by reason of the right of the party disposing of the property being subsequent to those which, without affecting the property of the thing sold, diminish the beneficial interest of the purchaser, such as a claim to a usufruct, or a rent issuing out of the lands. This warranty was either in law, being that security which every selling of a term, or from a judge during vacation, to enter up judgment upon it; if ten years old or more, by a rule to show cause. Many other regulations and restrictions exist respecting the operation of this kind of instrument, but they are of too technical a nature to be here discussed.

Warranty of lands in the English law is of feudal origin, and is derived from the obligation of the lord to defend his tenant's title against all claimants. If the tenant was evicted by another he must be restored to his possession by giving him other lands of equal value. Every tenant holding of his lord's time out of mind, by what was termed homage ancestral, was entitled to this warranty. The statute of the 18th of Edward I., commonly called the statute of Quia Emptores, which prohibited the practice of subinfeudation, and authorized the free alienation of property, put an end to the homage ancestral, and consequently to the implied warranty annexed to it. To avoid the effect of this, when the lord aliened, the tenants, before they left himself, reserved or reserved to himself a certain sum of money, which he might, on the death of his ancestor, have entered upon any lands aliened without his consent, the covenant of warranty descending upon the heir operatively as a confirmation of the title, and thereby obliging the heir who evicted him to yield the grantee a recompense in lands of equal value. This doctrine, it is said, was founded on the supposition that the ancestor would not wantonly disinherit his heir, who therefore was entitled to a recompense of the money which had purchased land, and that this equivalent descended to the heir, together with the ancestor's warranty.

P. C. No. 1689.
Warranties are of two kinds: first, warranties in deed, or express warranties; and secondly, warranties in law, or implied warranties. A warranty in deed, or express warranty, can be properly understood only by the use of the word warrant, or warranty. Warranties in law were so called because they were legal warranties without the use of the word warrant. If, after a partition or exchange of lands of inheritance, either party or his heirs be evicted of his share, or his interest in the land thereby lost, and upon a gift in tail, or lease for life, rendering rent, the donor, or lessor and his heirs, are bound in law to warrant the title. Warranty in deed was either lineal or collateral. Lineal warranty was where the heir derived, or might be an heir, and was held so long as his title remained, and if the land neither was nor could have been derived from the ancestor who made the warranty; for instance, where a younger brother released with warranty to the disseisor of his father, and then died without issue: this was a lineal warranty to the ancestor's estate. But if the conveyance to which the warranty was annexed followed immediately upon a conveyance, in the same cause, as where a man who had no right entered upon lands and made a conveyance of them with warranty, or where a father, being desirous to sell the same lands to two sons, made a conveyance in fee with warranty; this, which was in its commencement founded on the wrong of the warrantor himself, was called a warranty commencing by discession, and was not held binding on the heir of the tortious warrantor.

The obligation of the heir in both lineal and collateral warranty was founded on the supposition of his having other sufficient lands or assets descending to him from the warranty, or the owner thereof. The heir who bought without land had assets to insure the title of the alienee; yet in the case of estates in fee simple, the heir was barred by lineal warranty from claiming the estate, whether he had assets or not, on the ground that, by establishing his claim to the estate, he deprived the vendor of the gain made by him, and would thereupon become bound to fulfill his ancestor's warranty. But the rule did not extend to estates tail, the right to which was not barred by warranty unless the heir actually had assets in fee simple from the same ancestor, nor were estates tail, under warranty, subject to the same hardship and inconvenience of this doctrine with respect to collateral warranties were found to be so great, that various statutes were from time to time passed to restrain its effects. The statute of Gloucester, Edw. 1., c. 5, declared that a warranty of lands by a father, tenant in tail in fee simple, should be no bar to the son claiming his paternal inheritance, unless assets descended to him from the father. The 11 Hen. VII., c. 20, enacted that notwithstanding any hereditary warranty by the grantor in the conveyance of the husband should not be barred, though he were also heir of the wife. And by the 4 & 5 Ann., c. 16, all warranties by any tenant for life were made void against those in remainder or reversion, and all collateral warranties by any person after the death of the tenant in tail, and no estate in possession, were void against the heir. As this last statute did not extend to estates of inheritance in possession, a tenant in tail in possession until lately might in some cases have made a good conveyance in fee simple by superadding to his grant a warranty, which, if accompanied with assets, barred the tenant's own issue by lineal warranty, and without them barred by collateral warranty such of his heirs as might be in remainder or reversion.

The doctrine of warranty was the foundation of the assurance by way of conveyance. [see ss. 44 & 45.] The use of warranties in conveyances has long been sup-

Perhaps your model was not trained on the context of this document.
so the seller refuses to receive them, they remain at his own risk.

There are certain rules which have been laid down with respect to sales of horses, one of the most common subjects of actions on warranty. The fact that what is termed a sound price is given for a horse, does not imply any warranty of that kind with respect to the health of the animal. If a horse has any disease, or has met with any accident which either does, or in its progress or results will diminish the usefulness of the animal, such a horse is unsound, and therefore a cough or temporary lameness which, though it may be curable and not permanent in origin, diminishes his present usefulness, is unsoundness. So any organic defect is unsoundness, and therefore a nervous horse cannot be considered sound. Roaring is unsoundness if it proceed from disease or organic defect; but crib-biting, it seems, does not with its private property a warranty that a horse was free from vice. A warranty of soundness is broken if the disease or defect existed at the time of the sale, though it could not then be detected, and should appear till some time afterwards. The question of the soundness of a horse is one measured within the province of a jury to determine, and therefore a court will not set aside a verdict on account of the mere preponderance of contrary evidence, nor on the ground of any mere suspicion of fraud. [Warren, p. 671; see Chitty On Contracts, 3rd edition, p. 347 et seq., and the authorities there cited.]

WARREN. A Free Warren is a franchise which gives a person the right to hunt without the aid of dogs, called game, within the precincts of a manor, or any other place of known extent, whereby the owner of the franchise has a property in the game, and a right to exclude all other persons from hunting or taking it. It is laid down by Sir William Blackstone, that originally the hunting and destroying game belonged exclusively to the king, and it is certain that this franchise, like that of a chase or park, must either be derived from a royal grant, or from prescription, which supposes a grant. The law is thus at the commencement of Bredon [1528], where it is stated that 'none can make a park, chase, or warren without the king's licence, for that is quod omnino et propter quod appertinet in proprias pecunias.' [V. Warren] that free warren was introduced into England by the Normans, and there are many instances of such grants by the English monarchs subsequent to the Conquest. It is now in the power of the owner to apprest, except by prescription, and even when held with the manor, it does not pass by a grant of the manor without the apportionment; nor, if it be held in gross, will it pass by a grant of the manor and apportionment. (3 N. & M. 671.) The right of free warren over the land of another might also arise under other circumstances, as when a man, having free warren over certain lands, alienated them, reserving the warren. (8 Rep. 108.)

A warren may lie open, and there is no necessity of enclosing it. The owner of a warren is entitled to have his dogs and hounds and the fowls of warren are partridges and pheasants, though some add quails, woodcocks, and water-fowl. (Termes de la Ley, 589.)

The grantee of free warren acquired thereby the right to appoint and keep at the time of sale the king called a warreneer, who is justified in killing dogs, polecats, or other vermin which he finds disturbing or destroying the game (Croc. Jus. 49), and by 21 Edw. I. s. 2, entitled De Malefactors,所有 forestier, parcer, or warreneer, and shall be the same as having in forests, parks, or warrens, who resisted and refused to render themselves.

The franchise of free warren has nearly fallen into disuse since the enactment of the modern statutes with respect to warrens.

WARREN, SIR PETER, K.B., was born in Ireland in 1703, and was descended from a family long settled in that country. Having gone early to sea, he received his first command in 1727, and had distinguished himself in various parts of the world, both by his good conduct and his good fortune, when, in 1746, he was sent out with a small squadron to surprise Louisbourg, the capital of Cape Breton. The town and the whole island surrendered on the 15th of June; and for this service Warren was immediately made a rear-admiral of the blue, and after his return home reassembled the beginning of his professional career. He was appointed second in command, under Anson, of a fleet sent out to intercept two French squadrons, the one bound for America, the other for the East Indies; when the former, whose object was the recovery of Louisbourg, was taken by him with the Medway, and, after the capture of Havana, was kept in the West Indies for some time. In 1747, he was appointed commander-in-chief of the British fleet and, after the death of Anson, was made admiral of the fleet, and in the autumn of 1747, in the height of a popularity to which he was contributed as well as by his public services, he had been returned to Parliament for Westminster. A few years after this, in 1762, the general estimation in which he was held brought him a more singular compliment—the inhabitants of Willesden, near the city of London, sent him their alderman, elected upon electing Warren, who had recently been made free of the Goldsmiths' Company, to the vacant post; the admiral declined the honour, and sent them a present of 1000. to purchase the money, thus proving to them his determination to persuade him to alter his resolution: it was in vain that he remonstrated with them; they persisted in their choice; and eventually he was obliged to pay the fine of 1000. to avoid serving. Warren died, after a short illness, on the 2nd of July, 1762, and was buried at Westminster, a monument to his memory being erected near his church.
The town is on the north bank of the Mersey, just above the junction of the Sankey Brook, which passes not far through the parish; and via the church and a row of streets irregularly laid out and narrow. The principal road between Liverpool and Manchester passes through the town, and formerly as many as seventy public carriages were running daily; but the formation of the Manchester and Liverpool Railway has almost entirely diverted this traffic. The streets are well paved, and lighted with gas; the houses are many of them old and additively built; but interspersed among them are a number of modern well-built habitations. The parish church was partly destroyed in the siege of Liverpool, and in 1799 a new church was erected. It is a large cruciform building of various dates, capable of accommodating nearly 1000 persons. The chancel is the most ancient part, and is a good specimen of decorated English character. The chancel arch is supported by four pillars, and the organ is placed in a fine lofty apartment.

Mr. Baines, in his 'History of Lancashire,' adduces evidence to show that Warrington was a Roman station, Verstum, the Varina of Ravennas; but the evidence is far from complete. In the time of the Conqueror the manor, called Wallintune, was held by the king, and the place then gave name to one of the three hundreds, now merged in that of West Derby. Warrington derived its importance from a ford over the Mersey, on the north side of which the town stands. At the end of the fourteenth century a bridge was erected, which was about a century after replaced by a more substantial one of stone. For this stone bridge one of wood on stone piers was substituted in 1812. In the civil war of Charles I. the earl of Derby, a Parliamentarian, was himself at one time in possession of a successful attempt, in March, 1643, the Parliamentarians from Cheshire, under Sir Wm. Brereton, and from Manchester, under Colonel Ashton, took the town in May or June that year. In the campaign against the Royalist Scots in 1645, Colonel Adolphus bought the town of the Royalists, strong, to surrender at Warrington. When Charles II. entered England, in 1661, he had a sharp skirmish at Warrington with the Parliamentarians under Lambert and at the same time was compelled to retire. In 1715 Sir George Booth, formerly a Parliamentarian, who had raised the royal standard, was stopped in his flight from Winnington Bridge, near Delamere Forest, in Cheshire, where he had been defeated by Lambert, by the Parliamentarians of Worthington, by a strong force in the Jacobite insurrection of 1715; and the bridge was cut down in the insurrection of 1745, to prevent the passage of the rebels. The duke of Cumberland passed through Warrington in his march to the north in 1746.

The parish of Warrington has an area of 12,263 acres, divided as follows:—

The town of Warrington was made a parliamentary borough by the Reform Act, and returns one member. The borough includes the township of Warrington and that of Latchford, with some detached portions of the town of Warrington, and the Cheshire side of the Mersey: it has an area of 1010 acres, with (in 1831) 422 houses inhabited, 26 uninhabited, and 2 buildings.
together 450 houses, with 439 families and 2156 persons. The portions of Thelwall township (or rather chapelry) in Runcorn parish, also in Cheshire, which are included, have only two houses. The population of the parishes thus

brought by the census of 1831 was 18,184, exclusive of

those in Thelwall. The number of voters in 1835-6 was 577; in 1838-40, 633.

The living of Warrington is a rectory, of the clear yearly

value of £200, and is no reversion. The perpetual curacies of Trinity and St. Paul's chapels or churches, in the town,

are of the respective clear yearly values of 130L. and 160L.

Holinhall or Hollin large chapel, of 160L.; and Burton-

wood chapel, of 96L. The value of Taunton is not ret-

urned. The value of the rectory of St. Peter's, of Warrington,

and in the archdeaconry and diocese of Chester.

There were in the parish, in 1831, one infant-school, with

50 boys and 50 girls; forty other day-schools of all kinds, with

403 boys and 416 girls; and 32 scholar's where school was

established in the return; making a total of 1706 children, or

about one in eleven of the whole population, under daily

instruction. One of the schools was a free grammar-school,

well endowed, with 40 boys; two others were also endowed,

one of 60 boys and 60 girls; and another was a school of industry,

partly supported by subscription, with 100 girls. There were at the same time sixteen

Sunday-schools, with 1334 boys, 1308 girls, and 42 scho-

Iars of sex not distinguished, giving 2984 children, or about

one in seven of the population, under Sunday School

instructian.

About the middle of the last century an academy for

superior education among the dissenters was established

at Warrington; and several eminent men, including Dr.

John Aikin, father of Mrs. Barbauld; Dr. Enfield; Dr. Priestley; Reinhold Forster, the naturalist;

and Gilbert Wakefield, were engaged in conducting it.

It did not however succeed. During the continuance of

the academy several works were published at

Warrington, including Howard's work 'On Prisons,' Mrs.

Barbauld's 'Conics,' and some other poems, and 'Mount

Pleasant,' a poem, the earliest publication of the late

William Roscoe. Dr. Percival was a native of Warr-

ington.

There are a public subscription library, a mechanics' insti-

tution, and a dispensary. (Baines's History of Lancashire; Parliamental Papers; Clergy List; Pulpit, and Diocesan}

WARSOW, formerly the capital of all Poland, and now

of the kingdom of Poland, of which the emperor of Russia

is sovereign, and of the government Mazovia, is agreeably

situated on an eminence on the left bank of the Vistula, in

82° 20' 30" W. long. and 51° 47' 30" N. lat.; it is

itself, which is divided into the Old and the New Town,

and of several suburbs, among which Praga, on the right

bank of the Vistula, over which there is a bridge, is some-
times reckoned. The city is not regularly fortified, yet it

is a very strong citadel, which was erected, completely

commands it. The circumference of the city and

suburbs (including Praga) is ten miles, but there are many

gardens and fields in this area. The city itself is irregu-

larly built and the streets are narrow, but the suburbs, espe-

cially those called the New World and the Craweb

suburbs, are distinguished by their regularity and fine build-

ings; it is probably with these in view that Cannabich

says (in 1836) : 'Warsaw has latterly become one of the

largest cities of the world. An additional reason for this

change is the enlargement of the city proper, and the

inclusion of the suburbs; the mean wooden houses in the remote streets gradually dis-

appear, and others of stone take their place.' Among the

public buildings the most important are the Academy

of Sciences, which was transferred from Cracow to

Warsaw; 2, the Saxon palace, with a fine garden; 3, the

palace, formerly the residence of the prince, since

occupied by the commissariat department; 4, the Krasinski

palace, a very fine building, now the palace of the govern-

ment; 5 and 6, the palaces formerly belonging to Prince

Radziwill and Count Bruhl; 7, the university (now sup-

pressed); 8, the arsenal; 9, the new mint; 10, Marieville,

an imitation of the Palace Royal at Paris; 11, the military

hospital; 12, the railway station; 13, the Royal Mint;

14, the 100th palace of the Polish nobles; 14, fourteen

mons' and four nuns' convents (some of them have been suppressed)

with churches, and many other churches, a few of which

are remarkable; among them are the cathedral, the

church of the Holy Cross, that of St. Alexander (built

by permission of the pope), and the church of St. Nicholas in 1829, for the purpose of discharging the

national debt and promoting trade and commerce; a

founding hospital, six other hospitals, an agricultural academy, a deaf and dumb asylum, and numerous schools.
The capitular residence of the abbot of Warrington is

and probably amounts to nearly 150,000 inhabitants, of

whom 30,000 are Jews. The manufactures are of many dif-

ferent kinds, and the trade of the city is considerable,

being chiefly in the cloths and leather goods of the

place.'

It is a great impediment to the foreign trade that the

Vistula is in possession of Russia, and this impediment

will continue as long as Rusalia persists in its very vigorous

prohibitory system against commercial intercourse with

Russia.

Before the Cracow gate stands the gilt bronze statue

of King Sigismund III. on a marble column 26 feet high.
The emperor Nicholas caused a splendid monument to

be erected in the church of the Capuchins, in honour of

Charles John III. of Poland; in the same church.

In 1830 the statue of Copernicus was erected before

the palace of the Royal Society of Friends of the Sciences,

and that of Prince Joseph Poniatowski, who lost his

life in the battle of Leipzig, in the Cracow suburb, both

executed by a sculptor named Tatzkivnitsch, under the

direction of Thorwaldsen.

We have given a rather less detailed account of Warsaw

than of some other great cities; but it is in fact more easy

to say what Warsaw was than what it is; the changes made

in it are very marked, and especially the number of

pedestrian thoroughfares, which make the town more

numerous, and a system, the manifest tendency of which is to

Russianize Poland, is followed up with unremitting perseverance. The university was abolished in 1834,

and its library of 150,000 volumes and all its other valuable

collections transferred to St. Petersburg; the Academy of

Sciences is dissolved: the provinces, formerly called Woi-

wodship, are to be henceforth called governments, as in

Russia, and the Polish names for circles and districts,

Obwodi and Poweti, are changed for the Russian names, Ujedzi and Okrugii. 'Many changes in Warsaw and the

kingdom,' says a letter from Poland, of the 7th of May, 1843,

'indicate that the great measure of reform projected by

the emperor will be steadily carried into effect. The work

of Westernization is much pressed, and especially the

prohibitory system, and a law against Jews, has

one Polish institution, one Polish name after another dis-

appear. Measures, weights, money, the division of the

kingdom into circles and districts, the superintendence and

management of the roads and rivers, all are Russian.

Warsaw has become a splendid city; and the paraphernalia

daily concerns of life, and, however inconvenient and dis-

agreeable this may be to the people, they gradually be-

come used to it, and the great work advances. The Roman

Catholics complain to heaven of the measures adopted with

regard to the church in favour of the Greek religion; but

who shall put a veto on the imperial commands issued

from St. Petersburg? We even believe that a new allocu-

tion of his Holiness which should complain of further in-

fringements of the rights of the Roman church, would be

lightly thrown away at St. Petersburg, and give rise to

issue of further ukases. While the clergy, with much zeal, hold fast to the antient faith, the people appear in general to be indifferent. There can be no greater proof of the

strength of the Greek religion in Poland, than the fact that

Easter has been observed at Warsaw this year; it was an

exact counterpart of Easter at St. Petersburg; there were

games of all sorts, rope-dancing, puppet-shows, dioramas,

equestrian exercises, shows of wild beasts, springs, in a

word, everything to which a purely Greek population

was accustomed at that season. The people of Warsaw in
general were quite delighted, especially as spiritual liquors were not wanting; even the higher classes did not keep away, but beheld from their carriages the amuse-
ments of the people. We think the Roman Catholic clergy
felt it would not be easy to describe. On the 29th of

April, the birthday of the emperor's eldest son, the grand-
duke Alexander, was celebrated in the most splendid manner, by divine service in all the churches, a parade of the armed forces, a grand ball at the residence of the military governor, and a general illumination. The magnificent church of St. Borromeo, now building at Warsaw, is to be finished this year. It is enriched with marble and various ornaments, and will indisputably be 'the handsomest church in the capital of Poland.'

</table>

 wart, the name of small tumours or excrescences which occur on the cuticle. Like all other epidermoid tumours, they are unorganized in their origin and course. They are generally of a conical form, embrace only a small extent of surface, are hard, insensible, and in colour are usually darker than the surrounding surface. In structure they have a radiated character. Their growth is slow, and they derive their nutrition from the crust over which they lie. The parts of the body on which the excrescences most frequently occur are the hands and face, although they are by no means confined to these localities. They are of an innocent character, and produce no ill consequences, except by pressure, when they occur in such parts as between the fingers and toes or on the eyelids.

When stimulated strongly, they generally get smaller or disappear altogether. Hence the best mode of treatment is the application of stimulants. It is however a curious fact that they often disappear under the use of the simplest remedies, when more violent ones have failed to affect them. The most effectual remedy is cutting them away. When this may be objected to, the caustic application is generally attended with silver, strong acetic acid, urausted tincture of iron, or by powder composed of abacetate of copper and salinum in equal parts, or the application of a hair-pencil dipped in sulphuric acid.

The thin integuments situated near the anus are often found to be the seat of excrescences having the character of warts. They are of all sizes, from a pea to an orange. When small, they may be removed by the application of the stimulants recommended above; and when large, they should be cut away with the knife.

WARTON, JOSEPH, D.D., was the eldest son of the Rev. Thomas Warton, professor of poetry in the university of Oxford, and afterwards vicar of Basingstoke, Hampshire, and Cobham, Surrey; and of Elizabeth, daughter of the Rev. Joseph Richardson, rector of Dunsford, Surrey. He was born at Dunsford, in the house of his maternal grand-father, in 1722; was educated, till he reached his fourteenth year, principally at home by his father; was then admitted on the foundation of Winchester College, where he was to Oriel College, Oxford, in 1740. Having taken his degree of B.A. in 1744, he was ordained to the curacy of his father's vicarage of Basingstoke; and here he officiated till he was removed, in February, 1746, on the death of his father to Chelsea, where he was curate for about a year. After this he held for a few months the curacy of Warton at Draycot in Hampshire, and then returned to Basingstoke. In 1748 he was presented by the Duke of Bolton to the rectory of Winslade, in the neighbourhood of Basingstoke, which he purchased for 100 guineas, and by which he was enabled to remove to London, and to become a resident of St. John's, Smithfield. He continued at Basingstoke his residence for four years, and then removed to London, where he became a resident of Lincoln's Inn.

After his return to England, Warton published an edition of Virgil, accompanied with a new verse translation of the 'Eclogues' and 'Georgics' by himself, and one of the
of Oxford. In 1750 he contributed a few pieces to "The Student, or Oxford and Cambridge Miscellany," amongst which was his "Progress of Discontent," one of the happiest of his humorous effusions. The next year he published his satire entitled "Newmarket," and some other pieces in verse. In 1755 he edited, with adding his name to it, a small volume, which appeared at Edinburgh, with the title of "The Union, or select Scots and English Poems," amongst which were several of his own, some predecessors published, some new. In 1754 he published, in an 8vo. volume, his "Observations on the Antiquity of the Poets of Spenser," a work which at once established his reputation both for true poetical taste and for extensive and varied learning. It was extended to two volumes in a second edition, which appeared in 1755.

In 1757 Warton was elected professor of poetry; and in the course of the lectures which he delivered while he held that office he introduced his translations of pieces in the Greek Anthology now printed among his collected poems, and also his dissertation on the "History of the Poets of the Greeks, which he afterwards prefixed, in Latin, to his splendid edition of Theocritus, published, in 2 vols. 4to, in 1770. In 1758 he published, in 4to, a treatise now become rare, entitled "Inscriptions Romanarum Monumentorum Delectus," which was translated into English by Dr. Johnson's periodical publication, "The Idler." In 1766 he published, in 4to, a "Companion to the Student, or an Account of the City, College, and Cathedral of Winchester." This was followed the same year by a poem of dexterity, entitled "A Companion to the Guide, and a Grales to the Commentaries," being a complete supplement to all the "Commentaries of Oxford Houses," published (in 1754), and which he went through three editions. Soon after this he wrote for the "Biographia Britannica" the life of his "Thomas Pope, which he engraved by Jones, in 1772 and 1774, with some additions, corrected and enlarged. In 1761 he produced, in an 8vo. volume, in Latin, "Institutiones Rerum Divaricatarum," which was afterwards translated by his brother, and published in 1772 and 1774. Next year appeared the second and more enlarged edition of "The History of the Poets of the Greeks," the first and second editions having been followed by an impression of the third edition in 1765.

In 1766 Warton became head master of Winchester College. He was created Bachelor of Arts and Doctor of Divinity in 1772, and in the latter year married Miss Lambourne, daughter of Robert Lambourne, esq., in 1772 he was translated to his present see; and then Bishop of London became a canon of Westminster Abbey, and was made dean of Westminster. In 1773 he received the living of Croydon. In 1774 he was created a baronet, and in 1775 a fellow of the Royal Society. After this he commenced a series of his works with his "Notices of the Colleges and Schools of the University of Oxford." In 1786 he published a "Select Collection of Poems," which was followed by a companion collection of English Poems. In 1788 he was created a knight of the Bath, and in 1789 he was made a member of the British Academy. In 1790 he was made a fellow of the Society of Antiquaries. He died in March, 1790. He was one of the leading spirits in the literary world, and was universally admired for his kind disposition and amiable manners. He left a very considerable fortune, and was one of the richest men in the kingdom.
unfinished: of the fourth volume only about ten sheets were found to be printed at his death, bringing down the history to the year 1170. This was the same Henry VIII. of the reign of Elizabeth. There have been two recent editions of it in 2 vols., with the addition of much new matter in the form of annotation, but without any continuation of the narrative: one in four volumes, by the late learned and accomplished Mr. Richard Price, London, 1834; the other in three volumes, forming a reprint of Mr. Price's edition, with additional notes, which was brought out by the care of Mr. Richard Taylor, in 1840.

Warton made a collection of those of his poems which he thought preserved, and published it in 1777; and other editions followed in 1778, 1779, and 1789. He was made poet-laureate on the death of William Whitehead; and the same year he was elected Camden Professor of History at Oxford, and engaged by Eng. Dr. William Scott (the late Lord Stow). In 1785 also he published an edition of Milton's Juvenile or Minor Poems, copiously illustrated with learned and curious notes, of which a re-impression, prepared before his death, appeared in 1791. A Life of Warton was prefixed to a new edition of his Poems, by Mr. Mant, in 1802.

Thomas Warton, having produced no poetical performance of any considerable length, can only be reckoned as one of the chief of the minor poets; but among those he occupies a high place—not in the first rank, with Collins and Gray, but perhaps in that next to them. His poetry, without including his Pindaric odes, which, although they are also superior to many, may be dispensed with in the estimate of his merit, possesses three qualities: the descriptive, the romantic, and the humorous; and in each of these kinds of writing he has shown much more than mere taste and imitative power. He had at least both the candid eye, if not much of the 'fine frenzy' of a poet, and wrote with much more ease, although he perhaps the most passionate, impulses. There are not many things of the kind in the language, except in Prior and Swift, better than his 'Progress of Discontent'; his lines 'To a Lady' and 'In the Midst of the Year' have much of the picturesqueness, as well as true natural feeling, of Milton's 'L'Allegro' and 'Il Penseroso'; and his tale, or ode, as he calls it, entitled 'The Crusade,' is perhaps superior to any preceding attempt to re-awaken the echoes of our ancient romances in English.

WARWICK. [WARWICKSHIRE.]

WARWICK, GUY, EARL OF. Several of our mediæval chroniclers speak of this famous personage as having without doubt actually existed: Henry Knighton, for instance, who was born about the year 1230, or four centuries before this, gives a full account of his story in his 'Chronica de Eventibus Angliae' (printed in Twysden's 'Scriptores Decem,' pp. 2311-2743). And even in modern times several writers have been inclined to hold that his exploits had probably some foundation; but the date of the 'Red Book of the Earl of Warwick,' which does not appear in the Barony; but in his 'Warwickshire,' although he acknowledges that the monks have sounded out his praises too hyperbolically, he considers his story to be not wholly legendary or apocryphal, and even takes pains to fix the date of one of his achievements, his combat with the Danish champion, Colbrand, the giant, that same mighty man, 'as he is called in King John by Shakespear, who has also allusion to the same matter in his Henry VIII.' This battle, as the year 1180 to the year 1187 which Guy conceives, was in the sixty-seventh year of his age. Much more recently, Mr. George Ellis (in his 'Specimens of Early English Metrical Romances') has suggested that possibly Egil, an Icelandic warrior, who contributed very materially to the success of the ancient victors in Iceland, and was the king Athelstan over the Danes and their allies at Brunanburgh, 'becoming the hero of one of the many odes composed on the occasion of that much celebrated battle, may have been transformed, by some Norman monk, into the picturesque and romantic figure of Guy of Warwick.' Mr. Price, the late editor of Warton's 'History of English Poetry' (ii, 2), 'at best is but conjecture, nor can it be considered a very happy one. ... The initial letters in Guy, Earl of Warwick, are the representatives of the Teutonic W, and closely point to some cognomen beginning with the Saxon Wæg (bellum). Guy, in fact, must be considered as a personage belonging not to history, but to fable and romance. Camden was perhaps one of the first inquirers among us, if not the very first, who ventured to intimate so much, when in giving an account of the earlier days of his 'Britannia' (Warrickshire) he wrote (as Bishop Gibson has translated the passage), 'To pass by Guar, and Morindus, and Guy, the echo of England [the Latin is, Anglicae tympanum, meaning rather the drum of England, that is, the most resounding of English names], with many more of that stamp, which the fruitful wits of those times brought forth at one birth.' Ritson, in his 'Dissertation on Romance and Minstrelsy,' prefixed to his 'Antient English Metrical Romances,' pp. 91, &c., has taken some unnecessary pains to establish the nonhistorical character of Guy.

Even as a hero of romance Guy can scarcely be traced with certainty to a more remote date than the earlier part of the fourteenth century. Guy of Warwick, Ritson observes, is mentioned by the English chroniclers Robert de Brune, or Peter de Langetoft, about 1340. Among the romances of price enumerated by Chaucer in his 'Rime of Sir Thomas, in the 'Canterbury Tales,' are mentioned those of Bevis and Sir Guy' (line 18,827). Bishop Percy, in his 'Reliques of Antient English Poetry,' prefixed to his 'Antient English Metrical Romances,' remarks (p. 33) that 'the Romance of Sir Guy was written before that of Bevis, being quoted in it.' In this place Percy gives an account of various manuscripts of the romance of Sir Guy, the manuscripts being chiefly connected with the story of Sir Tristrem. Percy (vol. iii., pp. 100-117) has published two old English poems, 'The Legend of Sir Guy,' and 'Guy and Amaon.' There are no extant detached remains of the descriptive, the romantic, and the humorous; and in each of these kinds of writing he has shown much more than mere taste and imitative power. He had at least both the candid eye, if not much of the 'fine frenzy' of a poet, and wrote with much more ease, although he perhaps the most passionate, impulses. There are not many things of the kind in the language, except in Prior and Swift, better than his 'Progress of Discontent'; his lines 'To a Lady' and 'In the Midst of the Year' have much of the picturesqueness, as well as true natural feeling, of Milton's 'L'Allegro' and 'Il Penseroso'; and his tale, or ode, as he calls it, entitled 'The Crusade,' is perhaps superior to any preceding attempt to re-awaken the echoes of our ancient romances in English.
burbury in 1469, and was killed at the battle of Barnet, in 1471; as a condition of his surrender having taken place, his honours were forfeited, and George Plantagenet, brother of King Edward IV., having married Isabel Nevil, his eldest daughter, was created earl of Warwick and Salisbury in 1472. Clarence was put to death and attained in 1478, and his son died in 1483, but his rule over Warwick till he also met with a similar fate in 1489. From this time there was no earl of Warwick till the honour was conferred by Edward VI., in 1547, upon John Dudley, Viscount Lisle, who was maternally descended from the Beauchamps, Plantagenet, duke of Clarence; Beauchamp, twelfth earl. Dudley (afterwards created duke of Northumberland) was attainted and beheaded in 1553; but his second son, Ambrose Dudley, after being restored in blood, was created earl of Warwick in 1584, and on the 5th of that month raised himself to the title of earl of Warwick till he remained until 1616, when it was revived and conferred by James I. upon Robert Rich, third Baron Rich of Northumberland, and he was restored (from 1679 in conjunction with the earldom of Holland) by the same family till the death of Edward Rich, earl of Warwick and Holland, without male issue, in 1729. Upon this event the earldom of Warwick was conferred upon Francis Greville, first Earl Brooke, brother of his father, and was held by the line of Earls Brooke and Earl of Holland until the latter part of the eighteenth century, when the title became extinct, the title being then assumed by the descendants of the former, conferred in 1744, by a few years of earlier date.

WARWICK, RICHARD DE BEAUCHAMP, EARL OF K.G., was the son of Thomas, eleventh earl, and of Margaret, daughter of William, Lord Ferrers of Groby, and was educated at the royal household himself in the service of the state. He succeeded to the title upon the death of his father in 1401. In 1417 he was created earl of Arundel for life. In 1425, having been sent over to France with a reinforcement of 6000 men, he was left by the king of France to act as regent of that kingdom during his own absence in England. While holding this post he carried on the war with great success, making himself master in the course of the next two years of the whole of the Conquest of France. On the return of the duke of Bedford to France in February, 1428, Warwick was called home by the English council, and appointed governor to the king, Henry VI., now in his seventh year, and lightho brought up under the care of the queen, Catherine of France. Warwick was the eldest son of Archbishop Vertou, and his mother was his cousin and heiress of Lord Willoughby de Broke and his wife, Elizabeth Beauchamp, who was descended from Walter de Beauchamp, baron of Alcester and Towyc, thirteenth earl of Warwick, the highest and earliest earl, and brother of William de Beauchamp, who became earl of Warwick in 1267. In this family the titles of Earl Brooke and earl of Warwick still remain, the latter, contrary to what is usual, being the one commonly used, although the former, conferred in 1744, is by a few years of earlier date.

WARWICK, HENRY DE BEAUCHAMP, EARL OF K.G., was the son of Richard, twelfth earl, whom he succeeded, and was educated at the royal household himself in the service of the state. This earl of Warwick, who was styled the Good, left by his second wife, Isabel, daughter of Thomas Despenser, earl of Gloucester, a son, Henry, and a daughter, Anne, who married Richard, elder son of Richard Nevil, earl of Salisbury, creating in 1414 earl of Warwick.

The history of this mighty peer is that of the whole of the contest between the two houses of York and Lancaster from the first armed rising against Henry VI. to the overthrow of the Lancastrian forces in the fight of Barnet. Here we can only briefly note the most important events that marked his career.

He is first mentioned as being one of the leading magnates of the house of York, and having taken part in the march of the Lancastrian forces in the fight of Barnet. He was then called Henry de Beauchamp, his bravery on this occasion earned him the title of earl of Warwick, which was confirmed in 1419.
took up arms in 1455, he was joined both by Warwick and Salisbury; and the battle of St. Albans, fought 22nd May, was mainly won by the impetuous valour of Warwick. Immediately after this, while the office of chancellor was bestowed by the parliament upon Salisbury, Warwick was rewarded with the governorship of the north, and the sale of public offices. Under the very long time after the defeat of the Warsash, the most important military charge in Christendom. To this was added two or three years subsequently by Henry, who perhaps wished to attach to himself so able and powerful a subject, the custody of the sea, or the command of the fleet, for five years. It was in virtue of the latter appointment that, on the 29th of May, 1458, he set out from Calais with five large and seven small vessels, and, attacking a fleet of twenty-eight sail belonging to the free town of Lëbeck, captured six of them after a contest of six hours. But before their next attempt in the summer of 1459, Warwick came over from Calais with a large body of veterans, with which he joined his father at Liddlow, a day or two after Salisbury's victory over Lord Audley at Bloreheath in Staffordshire; and in the beginning of June following Warwick again landed in Kent with a force of fifteen hundred men; before he reached London, according to all reports, nearly all of his former friends or men had flocked to his banner; the capital, from which King Henry had fled, received him with all welcome; the battle of Northampton followed, on the 19th of July, at which Henry fell into the hands of the Yorkists. The next month in this fluctuating struggle in the battle of Wakefield, in Yorkshire, fought on the 30th of December, where the duke of York was defeated by Queen Margaret, and lost his life, and where the earl of Salisbury was taken captive, and beheaded the next day at Pontefract; and the queen's second victory over the Yorkists, commanded in this instance by Warwick, at Bernard's Heath near St. Albans, on the 17th of February, 1461, which restored Henry to liberty. But the junction, immediately after this, of the forces of Warwick and the young Edward, earl of March, now duke of York, compelled the royal army to retire to the north; Edward, accompanied by Warwick, entered London in triumph; on the 4th of March he was proclaimed king, by the title of Edward IV.; and on the 16th of March the earl of Westmorland in Yorkshire secured the throne to King Edward. On this occasion the main body of the Yorkist army was commanded by the earl of Warwick; who also, during the next two or three years, while the contest still lingered, persisted in his turbulent and independent course. In the winter of 1462-3 he reduced the three strong fortresses of Bamborough, Anwick, and Dunstanburgh; and it was to him also that the castle of Bamborough capitulated a second time, in May, 1464, after it had been made over to the Lancastrians by the decision of the governor, Sir Ralph Grey. Finally, it was Warwick by whom the unfortunate Henry was conducted to the Tower, on June, 1465, after his capture at Waddington Hall, about fourteen months after the final defeat of the Lancastrians at Hexham by Warwick's brother, Lord Montague. The Nevils were now in a manner the rulers of king and kingdom. Warwick himself, besides his government of Calais, held the post of chamberlain and the wardenship of the West Marches; his next brother, Lord Montague, was warden of the East Marches, and had obtained the extensive estates of the Percies, with the title of Earl of Northumberland; his youngest brother, George, was lord high chancellor; and his brother-in-law, Bishop of York. But circuits the title of Duke of Clarence, the Princess Margaret, with the duke of Burgundy, brought about in 1468, in opposition to the advice of Warwick; the seduction of the French king Louis XI.; the arts of Lancastrian emissaries; and, according to one account, an attempt made by Edward, in the earl's own house, to violate the chastity of his niece or daughter—were supposed to have been the principal causes that contributed to sever the king from the Nevils; but the story is too complicated, and, in many parts, obscure, to admit of being detailed, or investigated in any way. But at last, in 1470, when Edward died suddenly, the Nevils were once more in possession of York; but Edward's children, if not his nearest relatives, cannot be true. (See his 'Hist. Eng.', v. 190, note, edition of 1837.) The first open intimation of the loss by the Nevils of the royal favour was given in June, 1467, by the king commanding the archbishop of York to deliver up the在外 of the lord chancellor, then and for the future, to the king. Immediately after this there broke out in Yorkshire an insurrection of the peasantry, which, being joined by two near connections of Warwick's, the sons of his sister, Margaret, bride of George 2nd earl of Warwick, and the next year Warwick, who had retired, with a clouded countenance, to his castle of Middleton in Yorkshire, appeared again at court. But the hollow compact did not last long. In July, 1468, Edward's next brother, George, duke of Clarence, was killed in the battle of Wakefield, while the government of the country was actually transferred into an avowed attempt to drive the Wydlewilles from the management of affairs. The royalists were routed with great slaughter at Edgecote, on the 26th of July; and a few days after, Edward was taken prisoner by Warwick and the army of the archbishop of York. He was imprisoned at St. Albans, after his release, and then was conveyed to his castle of Middleton, under the care of the archbishop of York, for two or three months, during which Warwick twice defeated bodies of the Lancastrians who had risen in the north, and, counting upon his support of the crown, was made by the king, while he was held in bondage, a sovereign. But England was not yet at peace; the political events of the time, the operations of the French, and all the other dignities held by the late earl of Pembroke, whom he had been beheaded after the battle of Edgecote. Consequent upon this final defeat of the Lancastrians, the king recovered his liberty; but he was at large again before the end of the year, and apparently with the consent of Warwick. A new rupture, followed by another seeming reconciliation, took place in February, 1470. For in all those movements both parties were professedly aiming to gain time and opportunity to destroy one another. In the beginning of March an insurrection broke out in Lincolnshire, which soon very clearly appeared to have been instigated by Warwick and Clarence; but before they could get the advantage of it the royal army was defeated near York by the son of Lord Wels, the latter were defeated by the king's troops, on the 12th of March, at Erpingham in Rutlandshire. Upon this Warwick and Clarence fled first to the north; whence, pursued by the king, they returned to England. And having now the power of a sovereign, the guns of the batteries were turned upon them by the deputy, a Gascon named Vaucelles, to whom Warwick had entrusted the keeping of the place. On this they made for Harlfort, and were there received with distinguished honors by the admiral of France, and on the 15th of July, Warwick met Henry's queen, Margaret, at Amboise, and there the two solemnly agreed to forget the past, and to unite their interests and efforts for the future, sealing their compact by the marriage of Margaret with Edward, to Warwick's great joy. A force was now raised for the invasion of England; Warwick landed at its head, at Plymouth, on the 13th of September, and immediately proclaimed Henry VI.; Edward, who was in Yorkshire, fled to the town of Lynn, and there taking ship, on the 25th of September, was seen to escape to Alkmaar in Holland. On the 6th Warwick and Clarence entered London in triumph, and taking Henry from the Tower, conducted him with the crown on his head to the parliament, where he was formally restored by parliament to his offices of chancellor and archbishop of England and captain of Calais, with the addition of that of lord high admiral; his brother, the archbishop of York, was again made chancellor; his other brother, now marquis of Montague, for which title he had previously been forced to exchange that of earl of Northumberland, with the estates of the Percies, was restored to the wardenship of the East Marches. But all this lasted only a few months. On the 14th of March, 1471, Edward, secretly
assisted by his brother-in-law, the duke of Burgundy, landed at Ravengar in Yorkshire. First Clarence was won over, and then the archbishop of York. On the 14th April, 1450, at the battle of Barnet, and there the Lancastrians were defeated; and Warwick, their commander, and his brother Montague, slain. Their bodies were afterwards exposed for three days in St. Paul's, and then interred in the abbey of St. John in Berks.

By his first wife, Anne de Beauchamp, who survived him many years, and was after his death reduced to great poverty, till she was restored to her estates by act of parliament after the accession of Henry VII., the earl of Warwick left only the two daughters already mentioned. His eldest, Isabel, who died single, was the natural son of his husband, the duke of Clarence, who was put to death in 1478, a son Edward, who was styled earl of Warwick, and was beheaded on Tower Hill in 1499; and a daughter, Margaret, who was created countess of Salisbury in 1523 and married at the age of seventy, in 1541. By her husband, Sir Reginald Pole, knight, she was the mother of the celebrated Cardinal Pole, and of other three sons and a daughter. Warwick's second daughter, Anne, whose first husband, Edward, prince of Wales, was murdered in 1471, after the battle of Towkesbury, was married the next year to the duke of Gloucester, afterwards Richard III., and died in 1485. By Richard she had one son, Edward, who was born in 1473, and died in 1494. 

The earl of Warwick, or Duke of Northumberland, K.G., was the eldest son of Edmund Dudley, Esq., a grandson of the Lord Dudley, and famous or infamous as the instrument, along with Empson, of the extortions of Henry VII., for his share in which he was beheaded at the same time. His mother was Elizabeth Grey, daughter of Edward Viscount L'Isle (his father's second wife); and he was born in the year 1502. The attainer of Edmund Dudley was reversed the year after his execution; and his widow having in 1529 married Arthur Plantagenet, a natural son of the deceased, her brother, he was brought to court, where he attached himself to the suite of the reigning favourite, Charles Brandon, duke of Suffolk. This same year he received the honour of knighthood for the gallantry he had shown while attending the queen. He now began to have the influence with his successor enjoyed the patronage of Wolsey and Cromwell, the former of whom gave him, in 1535, the office of master of the armony of the Tower, and by the interest of the latter of whom, when Anne of Cleves was brought over, he was appointed master of the horse to the new queen. The fall of Cromwell, in 1540, did not deprive Sir John Dudley of the king's favour; as may sufficiently appear by his being raised in 1542 to the peerage by the title of Viscount L'Isle (which had been enjoyed by his mother), and by his second wife, Susanna, who died soon after being elected a knight of the Garter. In 1543 he was made lord high admiral for life. The same year, having been principally instrumental in the capture of Boulogne, he was appointed to the government of that place as the king's principal; and in 1544 he was created earl of Warwick. He now became ambassador and protector of the Realm. It had been originally intended to make him lord of Coventry; but on the 17th of February, 1547, he was created earl of Warwick, his pretension to which antient dignity consisted in his mother having been the daughter of the first earl of Warwick, and of the right which her father was Margaret Beauchamp, a daughter, by his first wife, of Richard Beauchamp, earl of Warwick, who died in 1439. Before the end of the year also he exchanged his post of high admiral (which was wanted for Somerset's brother), on the 1st, for the viscountship of L'Isle, for that of lord great chamberlain (which Somerset had himself held, and now gave up for his own sake; for he was lord high treasurer and earl marshall, forfeited by the recent attainder of the duke of Norfolk).

Warwick had greatly distinguished himself in the expedition to Scotland in the autumn of 1547, and in the battle of Pinkney, gained over the Scots on the 10th of September; and when he was found marching with an armed force against the Norfolk rebels in the summer of 1549, 'that noble chiefman and valiant earl,' as Holinshed calls him, was thought the fittest person to be entrusted with the command; for such, continues the chronicler, in the opinion of the people, was believed to be the most fit for the high manhood, valiant prowess, and great experience in all warlike enterprises, sufficiently tried and known to rest in him, that either they might be vanquished and overcome by him, or by none other. They were in a great attack, and that force did them such an order as was not engaged at Dussindale on the 10th of August. Soon after this we find Warwick openly disputing the supremacy with the Protector. According to Burnet, his instigator was the ex-chancellor Southampton, who, although no longer taking any share in the government, was, at this time, also exerting all his industry to make a party against Somerset.

The earl of Warwick, observes the historian, 'was the fittest man to work on; him therefore he gained over to his side and, having formed a confidence in him, he showed him all those favours for which the Protector triumphed: he had won the field of Pinkney, near Musselburgh, and had subdued the rebels in Norfolk; and, as he had before defeated the French, so, if he were sent over thither, new triumphs would follow him: he was below the age to be employed; besides, he engaged him to quarrel in everything with the Protector, all whose wavy motions were ascribed to fear or dulness.' The course and issue of the contest between the two rivals are related under the head of the Protector. He esteems his deposition from his office of Protector and sent to the Tower in October of this year; and then there was an apparent reconciliation between the old and the new dictator, during which, in the beginning of June, 1550, Warwick's eldest son, Lord L'Isle, was married to the lady Anne Seymour, Warwick was created duke of Northumberland on the 11th of October, 1551; and Somerset was brought to the block on the 22nd of January, 1552. In the beginning of May following the duke of Northumberland's son, the Lord L'Isle, died, and was married to the Lady Jane Grey, daughter of Frances, Duchess of Suffolk, and great-granddaughter of Henry VII., through her daughter the Princess Mary, who had been married first to Louis XII. of France, and then to Charles Brandon, Duke of Suffolk, and died on the 12th of November, 1553, on the succession by will to Lady Jane Grey (or Dudley). The event was kept concealed for a few days; but at last, on the evening of the 10th, Lady Jane was proclaimed queen. On the 14th, Northumberland left London at the head of 10,000 foot and 2,000 horse, as commander-in-chief of Mary he advanced as far as St. Edmund's-bury, and then returned to Cambridge, where, losing all hope, he proclaimed Queen Mary on the 20th. But the same day he was arrested by the earl of Arundel; the 18th of August he was arraigned of high treason, along with his eldest son, before the lord high steward, in Westminster Hall; both were found guilty, but only the father was executed; he suffered on Tower Hill on Tuesday the 22nd of August. To the general surprise, he professed in his last moments that he died 'in the true Catholic' (meaning the Roman Catholic) faith; and that, notwithstanding his profession of Protestantism, this had been his real religion all his life.

By his wife, Jane, daughter of Sir Edward Sackville, who died in 1555, in his thirty-sixth year, Northumberland had eight sons and five daughters. Of the sons two died before their father, the eldest, Henry, having been killed at the age of nineteen at the siege of Boulogne, the 19th of September, 1543, in the third year of the reign of Edward VI., who was the son and heir apparent, and died without issue in 1558; the day after Warwick, and without issue in 1549. The earl of Warwick was at the siege of Boulogne, the powerful favourite of the next reign; the sixth, George, died, executed, along with his wife, Jane, daughter of Henry, 12th February, 1554, the seventh, Henry, was killed at the siege of St. Quentin. In 1557, the eighth died young. 

Warwickshire is a middle county of England, bounded on the north for a very small space
Derbyshire, on the north-west by Leicestershire, the line of separation being formed in great part by the Roman road, Watling Street; on the east by Northamptonshire, on the south-east by Oxfordshire, on the south and south-west by Gloucestershire, on the west by Worcestershire, and on the north-west by Staffordshire. The form of the county is tolerably compact. The greatest dimension or length is from the junction of the three counties of Warwick, Derby, and Stafford, in the north, to the neighbourhood of Long Compton, in the south, 50 miles; the greatest breadth is from the border of Worcestershire, near Redditch, on the west, to the border of Northamptonshire, near Rugby, on the east, 33 miles. There is a detached portion of the county on the west wholly enclosed by Worcestershire, in the neighbourhood of Bromsgrove; and another detached portion on the south-west entirely surrounded by Worcestershire and Gloucestershire. The boundary of the three counties is very complicated in this part. The area of the county is estimated at 637 square miles. The population at the time of the last census was 511,262. The population in the previous ten years increased: 1821, 274,392; increase, 20 per cent.; 1831, 336,988; increase, 23 per cent.; 1841. 402,121; increase, 18.4 per cent. The population has very nearly doubled in the last four years, it must be remembered, for 1831 is the only year (which we pretend to facilitate comparison with former articles) gives 375 in habitants to a square mile. In area Warwickshire is the twenty-fourth English county; in amount of population (still judging by the census of 1831), the eleventh, being next to Kent, the Metropolis, and Cheshire, and next in density of population, the fourth, being exceeded only by Middlesex, Lancashire, and Surrey. The enumeration of 1841 gives 483 inhabitants to a square mile. The county is situated between 51° 58' and 52° 42' N. lat., and between 1° 50' and 2° 50' W. long. The county town is 83 miles in a direct line north-west of the General Post-Office, London, or 92 miles by the road through Bampton, St. Albans, Dunstable, Stoney Stratford, Towcester, Daventry, and Stamford. The county town of Warwick, 41 miles from Oxford, and 209 miles from London, the nearest large town; by river, the Isis joins the Avon near Warwick, by Hatton, Berkswell, Meriden, and Maxtowe to Whitacre, where it unites with the third range. None of these high grounds are of much elevation, and they are all in the red sand and new red-sandstone districts. A range of hills near the red-sand sand, partly in the district, runs eastward from Warwick, or rather from Leamington Priors, by Dunchurch and Rugby to the border of the county, separating the valleys of the Leam and the Avon.

Warwickshire has no lofty hills, but the whole county is occupied by gentle hills of moderate elevation and in some places of considerable extent. The south-eastern border is skirted by hills composed of the lower formations of the oolitic series, overlooking the valley of the Stour and the Vale of Red Rose, so called from a colossal figure of a horse carved in the ferruginous sands of the slope of Edge Hill, now a part of the scene of that battle in the progress of Charles I.: it is 50 feet high and rises by one of much smaller dimensions. These oolite hills just appear on the border of the county, about Prior's Merton or Marton, between Daventry and Banbury; but the principal portion in Warwickshire consists of two ridges, with the valley between, each being bordered by a small brook which joins the Cherwell near Banbury in Oxfordshire, through which valley the road by Banbury and Gaydon to Warwick runs. The northermmost ridge, comprehending the Burton hills, Grendon Hill, Bitham Hill, Compton (or Edge Hill), Liverton Hill, Mollington Hill, and others, runs from north-west to south-east, dividing the valley just mentioned from a parallel valley drained by another small feeder of the Cherwell, and the valley on which the Ridgeway and the Great Stratford runs near Chipping Nuneaton. There are extensive quarries of gritstone, part of the oolite series, on Compton Hill: the stone is used for troughs and flagstones. The other ridge consists of two parts or branches, meeting at Knowl Hill: one part runs parallel to the Cherwell, and overlooks the valley between them; the other is nearly at right angles to the former, and runs southward, overlooking the valley of the Stour. This latter part of the ridge, known in one part as Edge Hill, possesses considerable interest as overlooking the scene of the battle of Edge Hill in the civil war of Charles I.: it is an elevated platform with a steep escarpment, commanding an extensive prospect over Warwickshire and Worcestershire as far as the Malvern and Abberley hills west of the Severn. The southern prolongation of Edge Hill consists of one county only, but detached, of slaty beds, such as Tyseley Hill, Broom Hill, Mine Hill, and Long Compton Hill. Brailes Hill is detached from the principal chains of hills, and is more advanced into the valley of the Stour: it has two rather lofty summits. The Leominster hills or downs, which form the north-ern extremity of the oolitic range of the Cotswolds, and skirt the valley of the Stour on the western side, are in the detached portion of the county west of Shipston.

The valley of the Stour and the Vale of Red Horse, which skirt the foot of the oolite hills, are occupied by the beds of the lias formation, which overlie the greatest part of the county south-east of a line drawn by Alderminster, Loxley, Wellesbourne Hastings, Monk Mead or Morrell, Upton, Marton, Stratton-on-Dunsmore (on the high road from London to Coventry), and Bearley, near Rugby, Luttrellworth and Coventry, and Willy. The lias forms its north-western limit a range of high ground, including Walton or Bath Hill, Morton Hill, Brampton Hill, Haddrige-upon-field, Dunsmore (or Hill), Heath, Stratton-on-stour, and Long Marston, the red marl and new red-sandstone group crop out, and occupy the valley of the Avon nearly as far as Rugby. The lias forms the cap or summit of several high hills, Red Hill, Burton or Barston Hill, Welcome Hill, Rime Hill, Black Hill, near Stratford, and Alcester, and is used for paving, for stone seats, and as mable for chimney-pieces; it is usually variegated in colour, but presents denticulated appearances.

The rest of the county, with one or two exceptions, is occupied by the formations of the red marl and new red-sandstone group; and forms part of the great midland red-sandstone region, having in the north-east high ground in Fecceham forest, west of Alcester, along which the Ridgeway runs. Another range of high ground forms a semicircle north of Henley-in-Arden, inclosing the vale of the Aire drained by the Aire (a small feeder of the Avon), whilst particularly intensive near Balsall Heath, near Birmingham, and a chain of heads rises near Warwick, by Hatton, Berkswell, Meriden, and Maxtowe to Whitacre, where it unites with the third range. None of these high grounds are of much elevation, and they are all in the red marl and new red-sandstone districts. A range of hills near the red-sand sandstone, partly in the district, runs eastward from Warwick, or rather from Leamington Priors, by Dunchurch and Rugby to the border of the county, separating the valleys of the Leam and the Avon.

In Warwickshire there is a coal formation which extends in line sixteen miles from south-south-east to north north-west from Wicken or Wyken and Sow, two villages close to Coventry on the east, to the border of Staffordshire east of Tamworth; it has an average breadth of two miles. This valley runs in a general north-east, the inclination becoming greater towards the eastern edge of the field, where it is sometimes as great as 45°. The coal district is hilly, and the outcrop of the strata on the east forms a well-defined low escarpment, presenting in some places the coal-measures in an elevated strata of the millstone-grit. At the foot of the escarpment is a level plain, where the lower formations are covered by the red marl and new red-sandstone, which completely hides the coal strata, and the coal-measures are lost in the gravel and sandstone at Griff and Bedworth, in the southern part of the field, between Nuneaton and Coventry. Greenstone is found at Griff, resting to all appearance conformably between beds of shale.

Hydrography and Communications.—The greater part of Warwickshire belongs to the basin of the Severn; a considerable portion in the north is included in the basin of the Trent, and a small portion in the south-east to the basin of the Thames. No part of the course of the Severn drains all the county, except a branch of the River Stour into it by the Avon, one of its most important tributaries. The Avon rises in Northamptonshire, and crossing Watling Street under Dove Bridge, or Dot Bridge, the Tripontium of the Romans, enters Warwickshire about 12 miles from its source, for Dove Bridge. The river flows in a wide channel at Griff and Bedworth, in the southern part of the field, between Nuneaton and Coventry. Greenstone is found at Griff, resting to all appearance conformably between beds of shale.
by Stafford, Hampton Lucy or Bishop's Hampton, Charlecote and Stratford-upon-Avon; and from thence, partly within, partly upon the border of the county, by Wootton-upon-Avon, Burton Bridges, Welford, and Bidford, till it quits the county just above Harvington mill. Its course through the county may be thus estimated:—from Dove Bridge to the bend below Kyton 17 miles; from thence to Warton 14 miles; from Warton to Stratford 13 miles; below Stratford 13 miles: together 57 miles in this county; and if 12 miles be added for its course before entering the county, and 29 for its course after quitting it to its junction with the Severn at Tewkesbury, we have for the whole length of the river, 86 miles. The upper course of the river is winding, but regular; the sweep of it is about 10 miles, and the course 20 miles. The Anker rises in Wolvey Fields, between Wolvey, Withybrook, and Shilton; and flows north-west by Burton Hastings, Nuneaton, Mancester and Witherby, near Atherstone, Grendon, and Polesworth, into the Tame at Tamworth. Its whole course is about 26 miles. At Tamworth, the office line of the river is drawn on the left bank at Nuneaton, and the Sence, from Market Bosworth in Leicestershire, on the right, below Witherby, both very small. Part of the course of the Anker is on the border of Warwickshire and Leicestershire. Near the Tamworth it is navigable.

The small portion of the county which belongs to the basin of the Thames is drained by a small stream which rises near Burton Dassett, and flows south-east by Worthington into the Cherwell, below Banbury in Oxfordshire. The deficiency of river navigation of that county, and of the Avon below Stratford, is compensated by the number and importance of its canals. The Grand Trunk, or Trent and Mersey Canal, and Fazeley and Derbyshire the course of the Thames, running parallel to that river, sometimes on one side, sometimes on the other, and the first act for which was obtained A.D. 1768, may be considered as having given the first impulse to the navigation of the county, the whole of the Trent and the Grand Trunk is within that county. In 1768 the first act was obtained for the Coventry Canal, which commences in the Grand Trunk Canal, on Fradley Heath, near Alrewas, in Staffordshire, and runs southward, nearly parallel to the Trent, nearly a mile; the whole course is about 26 miles, and of that Dig., 17 miles; the remainder of which is navigable.

The Oxford Canal was commenced under an act obtained A.D. 1793, a year after the first act for the Coventry Canal. It commences in that canal at Longford, and has a winding course eastward to Ansty, or Ansty, on the road from Bedworth to Coventry, and then eastward to the Newbold-upon-Avon (where is a short tunnel) and Brownsover to Hill Moreton. From Hill Moreton it runs south to Brantston, where the Grand Junction Canal opens into it; then south-west by Lower Shuckburgh to Napton-on-the-Hill; and then southward, near Wombridge, through a tunnel 1188 yards, or two-thirds of a mile long, into Oxfordshire. It opens into the Thames at Oxford. The whole length of this canal is about 94 miles; of which about half is in Warwickshire or in Northamptonshire. From Newbold-upon-Avon, there are several small parts bound to which it crosses before finally quitting Warwickshire. From its commencement in the Coventry Canal it is level: within a mile of Fazeley a rise of 144 feet by two locks, and then a level of 6½ miles continues to Nuneaton, near Atherstone. Between Grendon and Atherstone (23 miles) is a rise of 514 feet, and from Atherstone the fall to Warwick is 39 feet in 3 miles.

The Anker rises in Wolvey Fields, between Wolvey, Withybrook, and Shilton; and flows north-west by Burton Hastings, Nuneaton, Mancester and Witherby, near Atherstone, Grendon, and Polesworth, into the Tame at Tamworth. Its whole course is about 26 miles. At Tamworth, the office line of the river is drawn on the left bank at Nuneaton, and the Sence, from Market Bosworth in Leicestershire, on the right, below Witherby, both very small. Part of the course of the Anker is on the border of Warwickshire and Leicestershire. Near the Tamworth it is navigable.

The small portion of the county which belongs to the basin of the Thames is drained by a small stream which rises near Burton Dassett, and flows south-east by Worthington into the Cherwell, below Banbury in Oxfordshire. The deficiency of river navigation of that county, and of the Avon below Stratford, is compensated by the number and importance of its canals. The Grand Trunk, or Trent and Mersey Canal, and Fazeley and Derbyshire the course of the Thames, running parallel to that river, sometimes on one side, sometimes on the other, and the first act for which was obtained A.D. 1768, may be considered as having given the first impulse to the navigation of the county, the whole of the Trent and the Grand Trunk is within that county. In 1768 the first act was obtained for the Coventry Canal, which commences in the Grand Trunk Canal, on Fradley Heath, near Alrewas, in Staffordshire, and runs southward, nearly parallel to the Trent, nearly a mile; the whole course is about 26 miles, and of that Dig., 17 miles; the remainder of which is navigable.

The Oxford Canal was commenced under an act obtained A.D. 1793, a year after the first act for the Coventry Canal. It commences in that canal at Longford, and has a winding course eastward to Ansty, or Ansty, on the road from Bedworth to Coventry, and then eastward to the Newbold-upon-Avon (where is a short tunnel) and Brownsover to Hill Moreton. From Hill Moreton it runs south to Brantston, where the Grand Junction Canal opens into it; then south-west by Lower Shuckburgh to Napton-on-the-Hill; and then southward, near Wombridge, through a tunnel 1188 yards, or two-thirds of a mile long, into Oxfordshire. It opens into the Thames at Oxford. The whole length of this canal is about 94 miles; of which about half is in Warwickshire or in Northamptonshire. From Newbold-upon-Avon, there are several small parts bound to which it crosses before finally quitting Warwickshire. From its commencement in the Coventry Canal it is level: within a mile of Fazeley a rise of 144 feet by two locks, and then a level of 6½ miles continues to Nuneaton, near Atherstone. Between Grendon and Atherstone (23 miles) is a rise of 514 feet, and from Atherstone the fall to Warwick is 39 feet in 3 miles.
The Staffordshire and Worcestershire Canal, the first act for which was obtained a.d. 1768, the same year as the Grand Trunk or Trent and Mersey Canal, may be considered as having given occasion to another part of the Warwickshire railways, though the latter county is in that county. In 1788, two years after the act for the Staffordshire and Worcestershire Canal was passed, an act was obtained for making a canal, called the Birmingham Canal, from Birmingham to Bilston in Staffordshire, now known to the Worcestershire and Staffordshire Canal at Atherley near Wolverhampton. In 1783 an act was obtained for making a branch to this Birmingham Canal, and for making another canal from Birmingham to the Coventry Canal at Fazeley near Tamworth; it passed the Birmingham and Staffordshire Canals were incorporated into one company, and by subsequent enactments have been enabled to extend their works. The Birmingham Canal, now called the Old Birmingham Canal, 224 miles long, including its branches, belongs chiefly to Staffordshire; little more than 2 miles being in Warwickshire. The Warwickshire part is on one level. The Birmingham and Fazeley Canal, 15 miles long, belongs almost entirely to Warwickshire, only 2 miles being in Staffordshire. There is a fall between Birmingham and Fazeley of 249 feet. There is a junction between this and the Old Birmingham Canal on the west side of the town of Birmingham.

The Worcester and Birmingham Canal was made under an act passed a.d. 1793; it commences in the Birmingham and Coventry Canal at King's Norton in Worcestershire, and runs south-east and then south into the Avon at Stratford. Of its whole course, 234 miles, by far the greater part belongs to Warwickshire. There are three or four short branches. The canal falls, from the Worcester and Birmingham Canal, to Stratford, 300 feet.

The Warwick and Birmingham Canal, made under an act passed in 1796, commences at Saltisford, on the north-west side of Warwick, and runs north-west by Hatton and Knowle to Birmingham, where it joins a branch of the Birmingham and Stratford Canal. The town of Birmingham. It is 224 miles long, and belongs to Warwickshire, except in one part in the neighbourhood of Birmingham, where it crosses a projecting portion of Warwickshire, a height of 186 feet above the summit level, 10 miles long, and then falls 42 feet to Birmingham. There is a short branch joining this canal with the Stratford-on-Avon Canal.

The Warwick and Napton Canal commences in the Warwick and Birmingham Canal near Warwick, and runs eastward by Leamington Prior, Radford Semele, and Long Itchington to the Oxford Canal at Napton-on-the-Hill. It was made under an act passed a.d. 1794; is about 14 miles long, rising 13 feet from Warwick to Napton, and belongs entirely to Warwickshire.

The Grand Trunk Canal, uniting the Mersey and its port of Liverpool with the Trent and its port of Hull, constitutes the main trunk or artery of this canal system of central England, in which Warwickshire is comprehended. The line of communication between this great line and the Severn, with its port of Bristol; and the Coventry, with the Oxford Canal, connected the system thus formed with the upper part of the Thames at Oxford, and the Grand Junction Canal with the town of Birmingham, is in fact the connecting link that brought the silk and ribbon manufactures of Coventry and its neighbourhood into communication with the four great trading ports of the kingdom; and the Old Birmingham and Staffordshire Canal annexed the iron district of Birmingham with the same ports. The communication with London and with Bristol was however circuitous; but the Worcester and Birmingham Canal gave more direct communication with Bristol; and the Warwick, Birmingham, and Warwick and Napton Canals, with London.

Of the coach-roads, the most important is the parliamentary road to Shrewsbury and Holyhead, which enters the county between Daventry and Dunchurch, and passes over Dunmow Heath and through Ryton, Coventry, Neth- den, and Birmingham. Two other main lines of road to Birmingham: one by Buckingham and Basbury, which enters the county at Shotwell, 4 miles from Banbury, and runs by Gaydon, Warwick, and Solihull to Bir- mingham; and the other by Oxford, which enters the county near Long Compton, and is about 6 miles north of the Ford-on-Avon, and Henley-in-Arden. The distance of Birmingham from the General Post-Office, London, by these three roads, is respectively 110, 118, and 120 miles. A road from London to Liverpool crosses the northern part of the county; and the lines of Birmingham and Burton upon Trent, passing through Atherstone; and the principal road between Bristol and the north of England passes through Birmingham and Sutton Coldfield in the northern part of the county. Roads lead from Warwick by Stratford to Daventry, and by Kidderminster to Coventry, and there are others of less importance.

There are several railways. The London and Birmingham was commenced under an act obtained a.d. 1833; and was opened throughout in September, 1838. It enters the county on the eastern side, not far from Rugby, passes by Rugby, Coventry, and Hampton-in-Arden. Its whole length is 112 miles, about 35 of which are in Warwick- shire. The Grand Junction Railway unites with the Lon- don and Birmingham at Warwick; the line through Wolverhampton, the Potteries, Nantwich, and Warrington to the Manchester and Liverpool Railway at Newton in Lancashire; and with the London and Birmingham, forms part of the great system of railway communication which unites the two principal cities of the kingdom, and between the manufacturing districts of the north of England; but only a small part of it belongs to Warwickshire. The act for it was obtained a.d. 1833, and it was opened throughout in 1837; its length is 624 miles. The Birmingham and Manchester Railway branches from the London and Birmingham line at Rugby, and runs by Leicester and Loughborough to Derby and Nottingham. The act was obtained a.d. 1836, and the railroad was opened a.d. 1840; it is 57 miles long, but only a very few miles of it are an extensive viaduct near Rugby. An act was obtained (a.d. 1837) for a railway between Manchester and Bir- mingham, but greater part of the line has been given up, and it unites with the Grand Junction Railway at Crewe in Cheshire. An act was obtained (a.d. 1840) for a railway from Birmingham to meet the Cheltenham branch of the Great Western Railway; it runs by Broomgrove, and is now completed; the length is 53 miles, but only a small part is in Warwickshire. An act was obtained for a railway from the London and Birmingham line at Coventry, Leamington Priors and Warwick, but we are not aware what progress has been made in it.

Agriculture.—This county, being situated nearly in the centre of England, opened the eastern and western borders to a healthy climate: except in the higher and more exposed situations, where the soil is cold and heavy, the harvest is as early as in more southern counties.

The soil varies extremely, so that two or three different kinds of soil are found in the same place. The chief soil is the loam, which is found to a considerable extent across the centre of the county, and especially between Warwick and Coventry, and from the borders of Worcestershire to Leicesetershire, is mostly of a superior quality; all of it very fit for white meadows, and bearing both beans and turnips. Where the loam inclines to sand, the subsoil is chiefly chesemont, marl, or sand- stone; and under the colder and heavier loams the sub- stratum is clay. There is also a fertile clay on limestone. The best soils, as is generally the case, are not cultivated
with that care and economy which would greatly increase their value. Where the tenant can get an easy livelihood without mean outlay, exertion, or risk, improvements are very slowly adopted. It is from the proprietors chiefly that improvements originate; and unless the tenant has the advantage of a capital tenement, he has little motive to
improving his farm. From various reasons of a political
care, and from old prejudices, there is a general
disinclination in landlords to grant long leases, and yet
nothing tends so much to improve a property. Some proprie-
 tors bring this to a fine, but many infer the danger of
like to see their tenants somewhat dependent on their good
will. The farms used to be of small extent formerly, but
many have been thrown together of late years, and there are now some extensive occupations. A great part of the
land is now considered as common pasture, so that tenants
inclosed, and, as a natural consequence, better farmed;
but many improvements might still be introduced, not
only in the course of cropping, but in the economy of lab-
our, especially in ploughing: few would be disposed to
might be employed in the more general adoption of
the light two-horse ploughs; some of the heavy loans may
require three horses to plough them when the soil is wet and
heavy, but it is absurd to use four horses and only make
the manure of the best. The county of Leicestershire
would better do well with two, at most three. Besides, a very wide furrow is seldom of advantage, whatever a deep one may be.

The course of crops on the best loans used to be:
—
a clean fallow—wheat, beans, oats or barley, and clover—and
the county of Leicestershire particularly, will do well after a
fallow. A better rotation is—fallow, barley, clover, wheat,
beans, oats—manured on the fallow and for the beans;
and if these last be well hoed and the land in good
heart, another crop of wheat may be taken after the beans,
include them as a manure for the following clover, and
they, together with turnips and mangold-wurzel, well manured, take the place of the fallow, and
are followed by barley, clover, wheat.

Lime is used in considerable quantities, and with very
good effect; it improves the quality of the wheat, and in
creases the crop.

On the light loams and sands turnips have been long
cultivated, but till lately not with the care which they de-
serve. They were generally sown broadcast, and thinned out
by hoeing; and the sheep were generally employed on
them as well as they could. This is now done on a much
improved system by some of the best farmers. The land
is better prepared, the turnips sown in drills over the
margins, and the roots are cut by a machine in the field,
and are put into pricks. The roots are cut out with chaff,
and oil-cake or meal: in this way the crop is much
heavier, and the sheep thrive better, while the land is
more richly manured. There is a great extent of excellent
pasture land in the Warwickshire, and although some of the
very best is liable to being infested with rabid land, and farmed on
the convertible system of husbandry, the landlords do not
readily give their tenants leave to break up old sward. It is
only on poor pastures that breaking them up may be advan-
tageous; and although more food is produced by arable land
for the public, the farmer will always prefer that system
which is most profitable to himself, and the landlord that
which ensures the highest and most regular profit. But pasture
land may be badly managed as well as arable, and much of
the same is to be found in Warwickshire; but the
Docks and thistles are allowed to grow and extend; and moles
and ants raise hills which diminish the useful surface; the
dung of the cattle is allowed first to burn the place where
it drops, and then to be carried away by insects.

And advantage of this latter, the custom of continually ploughing from the crown and
gathering the furrows, as it is called, had produced such
high ridges that a man might be hid behind them; and
the water always running down the steep sides of the
ridges, the wheat was springy and lodging. All the best soil was accumulated in the crown,
and there only the plants were vigorous. On a better system
being introduced, great difficulty arose in levelling these
high and always crooked ridges. The most scientific farmers
only avoid the danger of a large ridge of wheat by a
plain of broken stones or tiles barely covered with earth.
By twice gathering five or six furrows on each side of this
plain a little ridge was formed, and in course of time the
large ridge was split in two. As soon as cross-ploughing
could be effected, the whole was brought to a tolerable
level. The drains now were covered with a sufficient depth
of earth; but the old crowns were pared down to
the hard subsoil, and it took much time and patience, with
several fallows, to render them equally fertile with the
rest. In some fields not long levelled, ploughed in
straight and regular ridges, the wave of the crown of
the old ridge could be distinctly traced in the crop by a
deficiency in produce; while the old hollows were the
more luxuriant from the accumulation of fresh soil.

Thorough drainage is in the highest degree essential; but
where the subsoil is clay it will no doubt soon become
universal. The great superiority of the rich loams lying
on sandstone arises in part from being underdrained by
naturally, without which all their natural fertility would have
been lost.

There are not many water-meadows in the county, and
considering the copious springs which rise from the calcare-
ous rocks, and might easily be collected and carried over
the grounds situated at a higher level, it is surprising that
so little use is made of these advantages.

In the neighbourhood of Warwick, Coventry, and es-
pecially Birmingham, much land is laid out in gardens,
at a high rent, and well cultivated: pieces of meadow land,
and pastures, for feeding horses, may be seen near these
manufacturing towns. The mechanics delight in the light
spot of ground, in which they work themselves or employ
labourers, as a relaxation from their counting-houses and
workshops. These gardens are generally highly cultivated.

The growth of wheat, barley, and oats is not confined
to every estate of any extent, besides bedgerow timber, there
are woods and coppices. At one time the forest of Arden
occupied a large portion of the centre of the county. The
Stoneleigh estate, which is one of the finest in the county,
was formerly as extensive as it now is, and may have
been seen some years ago, and probably remain there still;
and also at Ragley, the marquis of Hertford's. The greater
part of the soil of the county is peculiarly adapted to the
growth of oaks. Coppice-wood is of less value in a dis-
trict where cultivations and pasturage are all of the same
class, though it is chiefly converted into hoops, hurdles, and hedges.

There are several thriving young plantations,
which will keep up the character of the county when the
old wood is cut down.

There is no breed of cattle peculiar to the county. The
dairy cows are chiefly long-horns, crossed in every possible
way: short-horns have been introduced, and are preferred
by many, especially for feeding, although the Herefords
are in great repute with the graziers; as well as Scotch,
whose flesh apparently is not so tough.

The old Warwickshire sheep is nearly forgotten, having
been superseded by the New Leicester and a cross of the
two breeds: for folding, the South Downs are preferred.

The following is a description of the field of the county
for the year 18...

At the time of the Domesday Survey the county contained ten hundreds; now there are four. The hundreds of Domesday were—Pexhoke, Hones-
berie, Tremelaw, and Bericestone, now comprised in Kineton hundred; Mereton, Stanley, and Bovelakow, now
comprehend the hundred of Kineton; and in the two latter it is
now comprehended in Barlichway; and Colshill, now
Hemlingford hundred. The position, area, and population in
1831 of the present hundreds, and their respective di-
visions, are as follows:
The borough of Warwick is included in Kineton hundred; Birmingham in Hemingford; and the county in the county of the same.

Warwickshire comprehends the city of Coventry, which, with the district, forms a county of itself [Coventry]; the county-town and municipal and parliamentary borough of Warwick; the municipal and parliamentary borough of Birmingham [Birmingham]; the municipal boroughs of Stratford-upon-Avon [Stratford-upon-Avon] and Sutton Coldfield; and the market-towns of Alcester [Alcester], Atherstone [Atherstone or Atherstone], Coleshill, Henley-in-Arden, Kenilworth, Kington, Leamington Priors, Nuneaton, Rugby, Solihull, and Tamworth.

Warwick, the county-town, is a place of considerable antiquity. It does not appear to have been a Roman town, though Camden and some others have regarded it as such. A charter of Beorhtwulf, king of Mercia, extant in the British Museum (capi. 44, fol. 15b), bears the name of 'Vicus Regalis Werburgewrie,' which is supposed to be Warwick. Warwick was ruined in the early wars of the Danes, and restored by the Lady Ethelfleda, daughter of Alfred the Great, and governor of Mercia, who built a fort on a hill near the town. At the time of the Domesday Survey, there was a borough and contained 261 houses, of which 130 belonged to the king. After the Conquest the town was protected by a ditch and walls, and the castle was much strengthened. Several religious houses were founded. In the time of Philip and Mary, the town received its first regular charter of incorporation, though it had sent members to parliament in the reign of Edward I.

The municipal boundaries comprehend the two parishes of St. Mary and St. Nicholas, the statistics of which in 1831 were as follows:

<table>
<thead>
<tr>
<th>Area in acres</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inhabited</td>
<td>Uninhabited</td>
</tr>
<tr>
<td>St. Mary</td>
<td>4560</td>
</tr>
<tr>
<td>St. Nicholas</td>
<td>476</td>
</tr>
<tr>
<td></td>
<td>1715</td>
</tr>
</tbody>
</table>

The municipal boundaries include the town, with a portion of the surrounding country extending from half a mile to above four miles from the town in different directions. The town is on the west side of the Avon, from which it is separated by Warwick Castle and the castle grounds. Its site is a solid rock, in which the cellars are excavated. The streets are irregularly laid out, but are spacious, well-paved, lighted with gas, and in general lined with modern well-built houses. The castle is one of the finest specimens in the kingdom of the antient seclusions of our feudal nobles; it has undergone many improvements, but the outward arrangement and form of the building have sustained little alteration. The approach to the castle is from the eastern part of the town, opposite St. Nicholas's church, by a winding path cut in the rock. One of the towers in the castle, known as Caesar's Tower, is the antient part of the whole building, and is of uncertain date; another, known as Guy's Tower, is of the latter part of the 14th century and of decorated English character, in fine stonework, of noble outline, and of curious construction and composition. The great hall of the castle, a noble room, 62 feet by 37, retains, in its appearance and furniture, much of its antient character. The other apartments contain a number of portraits and other paintings by the old masters, and a valuable and interesting collection of antient and modern armour. The grounds are extensive and beautiful, and one of the greenhouses contains the capacious and beautiful antient vase brought to England by the late Earl of Warwick, to whom it had been given by Sir William Hamilton, and known as the Warwick Vase.' St. Mary's church, built on the site of an old structure in the 14th century, and 'in great part rebuilt after a fire in 1694, which destroyed a large portion of the church, is in the centre of the town. It is a cross church, of which the choir and its windows, especially the choir-screen of Beuchamp Chapel, adjacent to the choir on the north side, are antient; the nave and transept are modern, and are of most barbarous architecture, with an absurd admixture of different styles. The choir has a finely designed arch, but the windows worked from the same stone on each side. 'The chancel,' says Rickman, 'is an uncommonly beautiful specimen of perpendicular work;' and the east front is remarkably fine—simple in its arrangement, but rich from the elegance of its parts. The beautiful Beuchamp Chapel, according to the same writer, 'is completely rich both within and without; its details of the most elegant character and excellent execution, and in very good preservation.' It consists of a chapel of several aisles, and a small aisle, or passage, on each side, between the chapel and the chancel of the church.

In the centre of the castle is a very rich altar-tomb, with the figure of Richard Beuchamp, earl of Warwick, whose executors erected the chapel according to the directions of his will; and there are some tombs of later date. St. Nicholas's Church is modern, neat in the interior, but small and altogether devoid of architectural beauty. There are a spacious and handsome county-hall; a large modern goth, adjoining the county-hall; a county house of the 18th century; and a town hall, or an ancient town-hall of respectable appearance; and a substantial market-house. 'Leicester Hospital' was originally two buildings, the halls of two guilds, founded in the reign of Richard II., one in honour of the Virgin, the other of the true cross, each for twenty-four masters, and an inn. The endowment of this hospital is of considerable value; the master now has, or is to have, a salary of 400l. per annum, and each of the brethren (who have been increased to forty) 80l. a year. The buildings consist of the brethren's lodgings and public kitchen, a quadrangle; a chapel of antient architecture over the west gate of the town; and an antient hall. An antient place of worship, called St. Peter's Church, over the east gate of the town, was used as a free hospital or almshouse. Other schools and almshouses, some dissenting meeting-houses, a neat but small building for the public library, and a theatre. There is a race-course on the west side of the town, where races are held yearly.

Some worsted and cotton piece manufactures are carried on at Warwick, but only 51 men were returned in 1831 as engaged in manufactures. There are malthouses, and lime, timber, and coal wharfs on the bank of the Warwick and Napton Canal. The market, which is well supplied, is attended, and the produce is carried to the market of Stratford on Avon and Coleshill. There are twelve yearly fairs, some of which are considerable cattle-fairs.

Warwick returns two members to parliament; the number of voters in 1835-36 was 1046; in 1839-40 it was 977; and the return for 1844-45 was 1038. There were two county wards, one for Warwick and one for Southam, and the principal place of election and one of the polling-stations for the southern division of the county. The assizes and quarter-sessions for the county are held here. The borough has a commission of the peace, and, under the Municipal Reform Act, is divided into two wards, each having a town council, consisting of 12 aldermen and 18 councillors. Its limits were not altered by the Boundary Act. Quarter-sessions for the borough are held, and there is a Court of Record for personal actions under 100l. but it is of little importance.

The living of St. Mary is a vicarage, of the value of 300l., with a glebe-house; that of St. Nicholas is a vicarage, of the clear yearly value of 216l., with a glebe-house. Both are in the rural deanery of Warwick, and in the archdeaconry of Southam.

There were in the borough, in 1833, twenty day-schools of all sorts, with 714 children, namely, 394 boys and 320 girls; three of these schools were supported partly or wholly by endowments, and contained 89 boys and 36 girls; three others, two of them national schools, were supported chiefly
by charitable contributions, and contained 60 boys and 120 girls. Of the population in the borough about one in thirteen was, in 1853, under daily instruction. There were at the same time ten Sunday-schools, with 865 children, viz. 303 boys and 362 girls; to which may be added one of the many schools which is also a Sunday-school, with 80 girls; making 945 children, or more than one in ten of the population, under instruction on Sunday.

Sutton Coldfield is in the Birmingham division of Hemlingford hundred, 7½ miles N.N.E. of Birmingham and 25 miles from London. The town, which is entered a free borough, enlarged and embellished the church, and introduced the clothing manufacture, building many houses which were to be free for such as followed that business. The parish has an area of 13,000 acres, and contained, in 1831, 757 houses, namely, 736 inhabited, 18 uninhabited, and 3 buildings; with a population of 750 families, or 3664 persons—about half agricultural. The town has a neat appearance, and contains some handsome houses. The church is handsome, and contains a pipe organ, and 27 Insurance society boxes. A grammar school

new in modern: the chancel contains the effigy of Bishop Vesey with his mitre and crozier; he died a.d. 1555, at the age of 103. On the town-hall, a neat brick building, are the arms of the prelate embazoned on a shield, surmounted with a crescent and star, and a noble and stately piece of architecture. The black and cheerless tract of 13,000 acres, extending into Staffordshire, and N.W. and W. of the town is Sutton Park, containing about 3500 acres, granted to the town by the Earl of Stafford, and part of the Lots of the manor, and contained some large pools or pieces of water. Some branches of the hardware manufacture, especially the manufacture of spades, saws, axes, and gun-barrels, are carried on. It has 10,000 daily instruction. The town market is on Monday; and there are two yearly fairs for cattle, sheep, and pedlery.

The corporation of Sutton Coldfield consists of a ward, two capital burgesses, and twenty-two aldermen; the title of the corporation is 'The Wardens and Society of the Royal Town of Sutton Coldfield.' It is not included in the Municipal Reform Act. The warden and the two capital burgesses are magistrates. Quarter-sessions are held, but their criminal jurisdiction has gone into disuse, and often consists of the King's bench, and the Court of Record is also disused. The borough is co-extensive with the parish. The income of the corporation consists of a rent of nearly 750l., and the interest of 1800l. 3 per cent. constable, and other just expenses; besides, the interest on the capital of the Corporation, viz. of the schools and ten almshouses, apprenticing two poor maid yearly, and other purposes chiefly charitable.

The living is a rectory, of the clear yearly value of which there is no return; in the rural deanery of Arden, in the archdeaconry of Coventry, and in the diocese of Worcester. There were, in 1838, ten day-schools, with 450 children, namely, 216 boys and 194 girls, and 40 children of sex not distinguished in the returns. About one in eight of the population was under daily instruction. Of these ten day-schools, six were endowed from the funds of the corporation; and there was, besides, a richly endowed but nearly useless grammar-school; the income of which was nearly 500l. per annum, but the scholars seldom amounted to five. The grammar school was a school of Latin only.

Coleshill is in the Birmingham division of Hemlingford hundred, about 10 miles E. by N. of Birmingham, and 18 miles N.N.W. of Warwick. The parish has an area of 6900 acres, and contained, in 1831, 404 houses, namely, 390 inhabited, 14 uninhabited, and 3 buildings, with 4044 persons, of which 1640 were males, and 2404 females. The church is dedicated to St. Mary. There is a square western tower with battlements, surmounted by a crocketed spire of late perpendicular character, of better design than execution. The church contains a font of Norman architecture, and is rich in monumental structure, especially in a fine entrance of a capital gateway of Norman architecture, in the lower part of an ancient tower surmounted by a spire of more modern date. But...
the most interesting object in the place is the castle, the ruins of which are extensive: they are principally of late perpendicular character, but there are some Norman portions. The most prominent part is an old tower called Caesar's Tower, of which three sides remain, with walls in some parts sixteen feet thick. The large and massive additions of John of Gaunt, known as Lancaster Buildings, are in different stages of decay; and the additions of the 13th to the 15th century, though of comparatively modern date, present, from the friable nature of the stone of which they are built, an appearance of great antiquity. They are called Leicestershire Buildings. They contain the ruins of the noble basement of the castle. The whole area occupied by the castle, and enclosed by the same earl is in better preservation, and is (or was, not long since) occupied as a farm-house. The ruins are in many parts mantled with ivy, which adds to their picturesque character, and are on an elevated, rocky site, commanding an extensive view of the country round.

There are very few remains of the monastery, which was first a priory, and afterwards made an abbey. It belonged to the Regular Canons of St. Augustine. Its possessions were valued at the dissolution at £132, 14s. 9d. gross, or 538l. 19s. (or, according to another statement, 536l. 15s. 4d.) clear yearly income. There is an ancient stone bridge over a brook flowing into the Avon.

The manufacture of horn combs, and of some chemicals, such as saltpetre, and sal-ammoniac, and Glauber's salts, is carried on at Kenilworth. The coal-manufacture, in 1831, employed 150 men. The market is on Wednesday, and there is a yearly cattle-fair. There are some dissenting meeting-houses in the town amongst which is a vicarage, of the clear yearly value of 280l., with a glebe-house, in the rural deanery of Stonely, in the archdeaconry of Coventry, in the diocese of Worcester.

There were in the parish, in 1833, five dame-schools, with 264 scholars, and 26 boys and 237 girls; and two other day-schools of all kinds, with 438 children, namely 201 boys and 237 girls; making one in six of the population of the parish under daily instruction. Of these schools, one was an endowed school with 66 boys, one a school of instruction supported by voluntary contributions, with 30 girls. Three others, with 43 boys and 33 girls, were supported either by endowment or by contribution.

One of the day-schools was also a Sunday-school, and there were two other Sunday-schools, who containing 114 boys and 124 girls, giving 255 children, or 14 per cent of the population, under instruction on Sunday.

Kington, or Kineton, is in the Kington division of the hundred, about 10 and a half miles south-east of east of Warwick. The antiquity of the name is disputed, and the place has no historical interest attached to it. There was formerly a castle situated on a hill west of the town; the ruins are popularly termed King John's Castle, and are said to have been built by King John's father, King John's Well. The area of the parish is 2540 acres, or, including the chapelry of Combrook, 3810 acres; it had, in 1831, 107 houses, namely 96 inhabited and 2 uninhabited; 152 families, and 820 persons. The chapelry of Combrook had at the same time 55 inhabited houses and 7 uninhabited; together 62: with 57 families, and 282 persons.

The population of the whole parish was 1102. The town is irregularly built, the principal street being along one of the roads from Barbury to Warwick; the houses are chiefly old, built of stone and thatched; there are however some detached modern houses. There is an old market-house in the market-place, which is small. The church retains some ancient portions amid many alterations: it is a cross church, with a square tower. The western door has a richly-moulded Norman archway. The market is on Tuesday, but is almost disused. There are two yearly fairs. The living of Kineton is a vicarage united with the chapelry of Combrook, of the clear yearly value of £76, 14s. 6d, in the gift of the Dean and Chapter of Lincoln, or of the Bishop of Lincoln, in the archdeaconry and diocese of Kington, and in the archdeaconry and diocese of Hereford. There were in the whole parish, in 1833, two day and Sunday schools (one of them a national school, and partly supported by voluntary contributions), with 120 children, namely 49 boys and 71 girls on weekdays, giving about one in nine of the population under daily instruction; and with 147 children, namely 68 boys and 79 girls, on Sundays, giving two in fifteen of the population under Sunday instruction.

Leamington Prior is in the Kenilworth division of Knightlow hundred. Its importance is quite of modern date, and is chiefly due to the establishment of Leamington Spa, which was noticed by Camden and Dugdale, but the valuable medicinal qualities of which were brought into notice by Dr. Kerr of Northampton, in 1784, whose recommenda-

tions attracted a few patients, and more prominently by Dr. Lambeth, about the year 1797. The parish has an area of 1720 acres, and contained, in 1831, 1103 houses, namely 1003 inhabited, 139 uninhabited, and 91 building; with a population of 1039 families, or 6599 persons, a very small part of which is agricultural. The town is 90 miles south-west of the General Post-office, and two miles east of Warwick. It is situated in the valley of the Leam, in a situation sheltered by gentle and well-wooded declivities; and consists of two parts, the old town and the new town, separated from each other by the River Leam, gardens, and shrubberies of the Royal Spa, and by the river Leam, which joins the Avon about a mile below the town. Leamington contains a number of new streets regularly laid out, well paved, and lighted with gas, chiefly in the New Town, which lies on the north side of the river, over which is a handsome stone bridge. The old well or spring noticed by Camden has a neat pump-room erected over it. Since 1784 new springs have been discovered, and in connection with these other establishments for making hot waters or baths or bathing, which are the principal, have been formed in different parts of the town. These establishments have hot, cold, vapour, and shower baths, and pump-rooms. There are a number of private and some public rooms, and lodging houses, and private houses, chiefly fronted with Roman cement. There is a handsome building containing a public library and reading-rooms, with an assembly-room above; another assembly-room has card, music, billiard, and refreshment rooms, and an art gallery; a theatre; a public promenade called the Ranelagh Gardens; a botanical garden; a parish church, which retains some old portions amid various mutilations and alterations; a modern episcopal chapel (St. Mary's); a place of worship for Unitarians; a Roman Catholic chapel; a place of worship for Baptists and Methodists; a place of worship for Dissenters; a perpetual curacy of the parishioners of the town; and baths for the poor. A market is held on Wednesday. The Warwick and Nuneaton Canal passes through the Old Town, and enables the inhabitants to obtain coal at a reasonable price from the neighbourhood of Birmingham.

The living is a vicarage, of the clear yearly value of £255: the value of the perpetual curacy of St. Mary's Chapel is not given. The parish is in the rural deanery of Atherstone, in the archdeaconry and diocese of Worcester. There were in the parish, in 1833, four dame-schools with 60 children, namely, 30 boys and 30 girls; a day and Sunday national-school with 134 children, namely, 100 boys and 34 girls; and twenty other day or boarding schools, giving 281 children, making a total of 726 scholars, or two in seventeen of the population under daily instruction. There were at the same time three Sunday-schools with 310 scholars, of sex not stated in the returns, giving one in twenty of the population under instruction on Sunday.

Nuneaton is in the Atherstone division of Hemingford hundred, about eight miles north of Coventry, or 101 north-west of the General Post-office, London. This town is indebted for its early prosperity to a number of the order of Fontevrault, founded here in the reign of Henry II., by Robert Bosse, earl of Leicester; the yearly revenues of the nunnery were valued, at the dissolution, at 290l. 15s. 4d. gross, or 233l. 14s. 6d. clear. It was the site of the old abbey of the very few houses of the order in England. The nuns obtained the grant of a weekly market in the time of Henry III. The hamlet of Ayleborough, about half a mile to the south-east of Nuneaton, in Nuneaton parish, may be regarded as one suburb, and the hamlet of Stockingford, two miles north of the town, another suburb. The small hamlet of Stockingford, in Nuneaton parish, is two miles west of the town. The statistics of the two parishes of Nuneaton and Chiltons Coton, in 1831, were as follows:—

<table>
<thead>
<tr>
<th>Towns</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nuneaton</td>
<td>7756</td>
</tr>
<tr>
<td>Chiltons Coton</td>
<td>2508</td>
</tr>
</tbody>
</table>
Only about a fifteenth part of the population of Nun
eaton, and a fifth part of that of Chilvers Coton, were
agricultural.

The town of Nuneaton is irregularly laid out, but
handsomely planted. The river Anker runs through
it. The church, which is enriched by a handsome chancel,
and next to it, is a Gothic building, with a square tower, but
too small for the accommodation of the inhabitants. The chief
branch of industry in the town and neighbourhood is the
raising of sheep. There are about four hundred houses
in the parish of Nuneaton, and 200 in the parish of
Chilvers Coton, besides women and children. The coal-
field, which extends from Tamworth to Coventry, passes
through both parishes, and there are some coal-pits. The
livelihood of Nuneaton is a vicarage united with the chapelry of Stock-
ingford, of the joint clear yearly value of 902L., with a glebe-
house, in the rural deanery of Arden, in the archdeaconry
of Coventry, and in the diocese of Worcester. The
livelihood of Chilvers Coton is a vicarage, of the clear yearly
value of 106L., with a glebe-house, in the same ecclesi-
astical divisions.

There were in Nuneaton parish, in 1833, eighteen day-
schools with 511 children, namely 91 boys and 390 girls,
and 390 children of sex not discriminated in the return. Two
of the schools were endowed: one of them was a grammar-
school founded by King Edward VI., with 49 boys; the
other, a day-school for girls, on the adjacent site, with
36 boys and 300 girls. One in fifteen of the population
was under daily instruction. There were six Sunday-schools,
with 789 children, namely 226 boys and 377 girls, and
125 children of sex not stated, giving about one in ten of the
population in the town and parishes of this portion of
Chilvers Coton there were at the same period one
infant-school, partly supported by an individual contributor,
with 49 children, namely 20 boys and 29 girls; four other
day-schools, two of them national schools, with 233
children, namely 146 boys and 87 girls; and one,
of 308 children, or one in eight of the population
under daily instruction. The two national schools were
also Sunday-schools, and were attended on Sundays by
120 boys and 80 girls; besides which there were five other
Sunday schools, with 24 boys and 118 girls: making a total
of 865 children, or two in seven of the population under instruction on
Sunday. From this unusually large proportion it is probable that
the Sunday-schools are from Atherstone or other adjacent
places.

There are several dissenting meeting-houses in the
two parishes.

Rugby is in the Rugby division of the hundred of
Kinglow, about 83 miles from the General Post-Office,
London, by the south aisle and 85 by the Birmingham
railway, from which Rugby is distant about a
mile. Rugby possesses no historical interest. It had
a castle in the middle ages, of which only the earth-works
remain, containing an area of 2190 acres; and
had, in 1831, 515 houses, namely, 496 inhabited, 7 un-
habitied, and 12 building; with a population of
496 families, or 2501 persons. The town stands on an eminence
near the south bank of the Avon, and consists of several
streets irregularly laid out, containing a number of well built
and handsome houses. The importance of the town is chiefly
derived from its grammar-school, founded a.d. 1567 by Law-
rence Sheriff, a native of Brownsover near Rugby, or perhaps
of Rugby itself, and a shopkeeper (some call him grocer)
of Leominster. In (1537) he had also some employ-
ment in the household of Queen Elizabeth, before her ac-
cession to the throne. The school buildings are in the
southern part of the town; the greater part of them
form a quadrangle laid out, containing a number long by 74
feet, and surrounded on three sides by open cloisters.
The buildings are in the Elizabethan style, of white brick,
with the angles, cornices, and dressings to the openings
and windows, of Attleborough stone. They were erected
early in the seventeenth century, and commanded a house of
spaciousness for the head-master, school-rooms, and a din-
ing-hall, private studies and dormitories for those scholars
who are resident under the care of the head master. There
is also a chapel erected since the foregoing buildings,
containing a monument of Doctor James, formerly
head master, under whom the school first rose to great
eminence. The principal buildings form the south side of
the quadrangle, with an eastward prolongation which in-
cludes the head master's house, and present a handsome
front toward the extensive play-ground of eight acres,
which lies on the south side of the school buildings. Rugby
Cot has a church which possesses little architectural interest. It has a
square western tower without buttresses and devoid of
ornament. There are two ranges of almshouses, one of
them endowed by Sheriff, the founder of the grammar-
school.

Rugby has a weekly market on Saturday, and eleven or
twelve yearly fairs, one of them a great horse-fair.
The Oxford Canal passes near the town. There are places
of worship for Baptists and Wesleyan Methodists.

The living of Rugby is a rectory, of the clear yearly value
of 510L., with a glebe-house, in the rural deanery of Marton,
in the archdeaconry of Coventry, and in the diocese of
Worcester.

There were in the parish, in 1833, six daily schools of all
kinds, with 625 scholars, namely, 455 boys and 160 girls,
giving about one in four of the total population under
daily Instruction. This unusual proportion is mainly
owing to the eminence of the grammar-school noticed
above, which commands curious great churches. The various
parts of the kingdom. The establishment of the school is
estimated to produce 5000L. per annum; a very valuable
part of it consists of eight acres of ground, now covered
with buildings, in or near Lamb's Conduit Street, London,
which were purchased for 100L. from Mr. De Vere, of
Elborow, and another, with 230 acres, was established a.d.
1830, by a gentleman who allowed the master 50L. a year.
There were at the same time two Sunday-schools, with
245 children, namely, 115 boys and 130 girls; giving one in ten
persons in the town, and perhaps some others, a
teaching. The church, which is on the south side of the
village, is a large tapering structure, with a large transept,
and part of the nave, with the lower part of the
tower, which rises from the intersection of the nave
and transept, are of decorated character, of an early date
and remarkable character. The west end of the nave
is a large window, with a fine spire of stone, and
the spire is the belfry-story of the tower. The spire, which is octa-
gonal, is modern. Attached to the chancel on the north
side is a small chapel, now used as a vestry, of similar archi-
etecture to the chancel, having under it a small but
attractive plain groined crypt. The windows of the
transept and nave are very good; the west window of the nave,
though of singular composition, is also good. The
chancel and the vestry have each on the south side a niche for
the vessels of the altar; that in the chancel is richly canopied
that in the vestry plain. The tracery and mouldings in
these parts of the church are very good; the corbels on
the wall of the chancel are very perfect, and deserve attention
for the spirit and beauty of their foliage. The piers of
the nave are plain, but the clerestory has a marvellous
plane screen work in the church. There are a meeting-
house for Independents and a chapel for Roman Catholic.

The market (if kept up) is on Wednesday, and there are
three, or, according to other accounts, five yearly fairs for
cattle, horses, cheese, or other articles.

The living is a rectory, of the clear yearly value of 1455L.,
in the rural deanery of Arden, in the archdeaconry
of Coventry, and in the diocese of Worcester. There is in the
village a chapel erected in 1455, to St. James, the curacy of
which is of 40L. clear yearly value.

There were in the parish, in 1833, thirteen day-schools of
all kinds, with 279 children, namely, 117 boys and 42
girls, and 120 children of sex not distinguished in the
returns; giving one in ten of the population under
daily instruction. There were at the same time four Sun-
day-schools, with 270 children, namely, 127 boys and 143
girls; giving about one in eleven of the population under
instruction on Sundays.

Southam is in the Southern division of Knightlow hundred,
13 miles north-east of the General Post-Office, Lon-
don, through Daventry, 9 miles cast by south of Warwick and
12 south-east of Coventry. The parish has an area of
2770 acres; and contained, in 1831, 289 houses, namely,
226 inhabited and 9 uninhabited, with a population of 286
souls: of which, 236 were males, and 50 females. About
one-third of the population was agricultural. The town lies
in a valley, watered by a small stream which flows into the Ithen, or Iечен, just be-
low the town. It contains a number of modern well-built
houses, and a number of various kinds of manufactures.
It is decorated with some good windows; other parts are
of perpendicular character, some parts very
good, others inferior. It has a western tower and spire.
Some of the tracery has been much mutilated. There
are a number of worship for Baptists, a free school, a self-sup-
porting dispensary, and an infirmary for diseases of the
eye and ear. The last is an ornamental building of per-
pendicular character. The market is on Monday, and is a
good corn-market; there are several yearly fairs for sheep,
horned cattle, and horses. There are two mineral-springs
near the town.

The living is a rectory, of the clear yearly value of 534£,
with a glebe-house, in the rural deanery of Marton, in the
archdeaconry of Coventry, and in the diocease of Worcester.
The population, in 1831, was 289, and in
the national schools, chiefly supported by endowment or con-
tributions, with 97 children, namely, 67 boys and 30 girls;
giving about one in thirteen of the population under daily
instruction. There were 17 average day-schools, and
were attended on Sunday by 101 children, viz. 73 boys and
28 girls, or one in twelve of the population.

A few of the villages claim a brief notice. Bedworth
is in the Kirby division of Knightlow hundred, about 3
miles south of Bidford. The church of the parish has an area
of 920 acres: the population, in 1831, was 3980, a very small part
of which was agricultural. There are coal-pits and stone-
 quarries near the village, which, in 1831, gave employment
to 180 men: more than 300 men were at that time engaged in
the employment of the quarries. The village is remarkable
for its beauty; it is situated on a rise, and is in
the same level as the population returns. The village is on the road between Nuneaton and Coventry, which are the chief seats of the ribbon-manufactory.

Birford is in the Stratford division of Barlichew hundred,
on the northern bank of the Avon, over which there is
a bridge 6 miles lower down than Stratford, on the line of the
Icknield Way. The parish has an area of 3240 acres,
with a population, in 1831, of 1293; above half agricultur-
al.

Brails is in the Brails division of Kington hundred, in the
south eastern part of the county, 10 miles from Banbury,
the road to Shipston-upon-Stour. The area of the parish is
3220 acres: the population, in 1831, was 1272; much of
the land is of an agricultural character. The
furniture of plough for livings. Brails had, in 1833, an infant-
school with 40 children; an endowed day-school with 104
boys and 10 girls; two national Sunday-schools; and
a small day and Sunday school, taught gratuitously by the
Roman Catholic priest; besides private schools. The
church is large, and has a lofty tower: some parts are
of early English, others of decorated English, others of per-
pendicular character. In the churchyard there is an
antique tomb with a effigy.

Bolton in the Kirby division of Knightlow hundred,
about 4 miles south-east of Nuneaton. The parish has an area
of 4000 acres: the population, in 1831, was 1782; nearly half agricultural. The village of Bolton
is about a mile from the church, which has been enlarged
in the last few years, is close to the village on the north-
side. In 1831, 166 men in the parish were engaged
in manufactures, chiefly or wholly in that of ribbons.

Dunkirk is in the Rugby division of Knightlow hundred,
about 6 miles south-east of Chippenham. The parish has
an area of 5010 acres, and comprehends the hamlets of Toft
and Thoristowe: the population, in 1831, was 1029; about
half agricultural. Dunchurch village is on the south-
eastern brow of the high waste land of Dunsmore Heath.
The parish comprehends the parish on the north.

The church is in a considerable
manding situation, and is a handsome and curious building.

The chancel is early English, with some good decorated
windows inserted, particularly the east window: this
chancel has the low side window. The nave is decorated,
with good piers and arches, and some good windows: the
doors of the aisles have remarkably rich mouldings. The
tower is perpendicular, with considerable enrichments
and mutilations. There are two ancient water-drains, and the
antient font is in the tower: it was plain and circular, with
a cabled moulding round the upper edge. There are
some small portions of an old wall, or workings, in the church
(Rickman). There is a substantial brick school-house for
the free grammar-school, which contained, in 1833, between
60 and 70 boys; and near the school-house is a range of
almshouses.

Dunsmore is in the county of the city of Coventry, about
4 miles north of that city. The area of the parish is 1750
acres: the population, in 1831, was 810; about one-third
or one-fourth agricultural: the ribbon-manufacture gave
employment at that time to above 50 men.

Poleshill is also in the county of the city of Coventry, about
2 miles north-east of Coventry. The area of the parish is 2910 acres: the population, in 1831, was 6968; a
very small part agricultural. This parish is one of the
principal seats of the ribbon-manufacture, which employed,
in 1831, 800 men in the manufacture. Poleshill has an Independent place of worship, and an endowed
free-school or schools. There are coal-works and a stone-
quarry near the village.

Sow is in the county of the city of Coventry, about 3 or
4 miles east of Chippenham. The area of the parish is 1090 acres: the population, in 1831, was 1414. The ribbon-manufacture gave employment to 100 men in
this parish, and to above 50 in the neighbouring parish of
Shipston (the area of which was 880 acres); and the popu-
lation, in 1831, 460, in the Kirby division of Knightlow
hundred. There are considerable coal-works in Sow parish:
the Oxford Canal passes through the midst of them.

Spoke is also in the county of the city of Coventry, about
3 miles south-east of Coventry. The area of the parish is
950 acres: the population, in 1831, was 848. The ribbon
or other manufactures employed about 53 men in 1831.

Stoneleigh is in the Kenilworth division of Knightlow hundred, on the road to Bromsgrove, which joins its junction with the Avon, about 2 miles east of Kenilworth, and 18 miles west of Warwick. There was anintently a Cistercian abbey here, transferred hither from Radmore in Staffordshire about 
A.D. 1154, the yearly revenues of which at the dissolution
were estimated at 1728. 2d. 5d. gross, or 1512. 0s. 4d. clear.
The gateway of the abbey is still standing in Stone-
leigh Park, the seat of Lord Leigh. The church of Stone-
leigh is a large irregular building, partly of Norman archi-
tecture, partly of later date. Among the monuments is
that of Miss Eager, daughter of Lord Chancellor Egbert,
wife of Robert Dudley, earl of Leicester, the favourite of
Queen Elizabeth, but could not establish her claim. The
area of Stoneleigh parish is 8030 acres: the population,
in 1831, was 1298; three-fourths agricultural. There are
two free schools, one for boys and 75 girls, in the week, and 106 scholars, 51 boys
and 57 girls, on Sundays.

Studley is in the Alcester division of Barlichew hundred,
about 4 miles north of Alcester. The parish has
an area of 5070 acres, and comprehends the hamlets
of Austin's and Thurstaston: the population, in 1831, was 1003; about one-third agricultur-
al. A considerable manufacture of needles and fishing
books is carried on in the parish, which gave employment, in 1831, to above 100 men, beside women and children. Wolfe, nearly 6 miles south-east of Nuneaton, had, in 1831, 46 persons engaged in manufactures, apparently of ribbons. The area of the parish is 3790 acres: the population, in 1831, was 995; two-fifths agricultural.

**Divisions for Ecclesiastical, Legal, and Parliamentary Purposes.**—This county is at present wholly included in the archdeaconry of Coventry. It comprehends the whole archdeaconry of Coventry and a part of the archdeaconry of Worcestershire. The rural deaneries and ecclesiastical curates are as follows:—

**I. Archdeaconry of Coventry.**

The archdeaconry of Coventry was formerly included in the diocese of Lichfield and Coventry; but, in pursuance of the recommendation of the church commission, has been separated from that diocese, and added to the diocese of Worcester, in which the whole county is now included. The archdeaconry of Coventry includes the greater part of the county, and especially the rich and populous manufacturing districts of the north and north-east. The archdeaconry of Worcestershire comprehends the southern and south-western parts, which are agricultural, together with the adjoining part of Worcestershire.

The county is included in the midland circuit; the assizes and quarter-sessions for the county are held at Warwick; those for the city of the county of Coventry at Coventry. There are a county gaol and county house of correction at Warwick; a gaol and house of correction at Coventry for the county of that city; lock-up houses at Leamington and Birmingham; a debtors' or Court of Requests' prison at Birmingham; and a county asylum for disqualified juvenile prisoners at Stratford.

The county gaol at Warwick is well ventilated and dry, and moderately clean; but so much crowded as to make it difficult to maintain effective discipline: the townspeople give more trouble than prisoners from the county parts; but the most troublesome are the debtors.

The county house of correction at Warwick has not a sufficient number of cells for the proper separation of the prisoners; but the management is such as to reflect the highest credit on the keeper and staff. The system of labour in the cells formed by the inspectors of prisons is deserving of imitation. Nearly half the prisoners are from Birmingham. The chaplain to the gaol and house of correction is a zealous and efficient officer, and some interesting cases of reformed prisoners are given by him in the Fourth Report of the Inspectors of Prisons. The gaol and house of correction at Coventry is not large enough, but the number of cells is sufficient for the usual number of inmates: it is secure, dry, and moderately well ventilated; and the management of the prisoners and weavers and agricultural labourers is good; some of them are strangers not resident in the county of the city of Coventry.

The two lock-up houses at Leamington are small and insufficient; one is under the town-hall, the other at the police station, in a distant part of the town; that at the town-hall, which is most used, has not a sufficient number of cells. It is used only for the temporary confinement or prisoners. The principal lock-up house at Birmingham (there are three lock-up-houses) is attached to the police office. The time of confinement is usually short, and there is little attempt at discipline; there is no chaplain, and no instruction of any kind is provided. The debtors' prison at Birmingham is exclusively for debtors from the Court of Requests; it is neglected and dirty.

The county asylum at Stratton was established in 1817, at the suggestion of Judge Dallas, for the reception and reformation of juvenile offenders at the expiration of their imprisonment. The house, now in a retired situation, is in the hands of a keeper and his wife, the only resident officers. The age of admission is from 14 to 16; but some boys under 14 had been received and transmitted to 'the Children's Friend Society' during the interval. The boys are taught to read and write and the elements of arithmetic, and are employed in making clothes and shoes, and in working in a large garden, in which they commonly take great delight.

There is an ample supply of books, religious and miscellaneous, and books, and have and become respectable workmen. Some have come afterwards, and expressed their gratitude for the benefits derived from their residence here. The institution is supported by voluntary contributions, and by the sale of articles made in the house.

Before the Reform Act, Warwickshire sent only six members to the House of Commons, namely, two for the county, two for the city of Coventry, and two for the borough of Warwick. By the Reform Act the number was increased to five. The county is divided into two parts; two each for Warwick and Coventry as before; and two for Birmingham, which was made a parliamentary borough. The Boundary Act the northern division of the county was determined to comprehend the hundred of Hemlingford, and the county of the city of Coventry, and the Rugby and Kirby divisions of Knightlow hundred: the principal place of election is Coleshill; and the polling places are Coleshill, Nuneaton, Coventry, Birmingham, and Dunchurch. The southern division of the county comprehends the hundreds of Barlichway and Kington, and the Kenilworth and Southam divisions of Knightlow hundred: the principal place of election is Warwick; and the polling places are Warwick, Kington or Kington Stratford-on-Avon, the Hey-in-Arden, and the city of Warwick. The county of Warwick, which is less extensive than that of the county of the city, and those of the borough of Warwick, were not altered by the Boundary Act. The parliamentary borough of Birmingham comprehends the parishes of Birmingham and Edgbaston, and the towns of Bordesley, Dudley, Dostington and Duddleston with Nechells, and Deritend, in the parish of Aston. The population of the parishes and townships included in the borough was, in 1851, 142,251. Birmingham has since been incorporated as a city, by charter dated 6th Oct., 1838. The municipal borough has the same limits as the parliamentary. The constitutional constituency of the county and the city and boroughs in it, in 1835-6, and 1838-40, was as follows:

**History and Antiquities.**—In the earliest historic period this county appears to have been or near the border of the three nations, the Cornubii (Kopeuros, Ptolemy; or in one MS. Kopeuros), the north-west; the north (Kepareus, Ptolemy), on the north-east; and the Dobunii (dotsuros, Ptolemy), on the south; but to which of these nations it belonged, whether to one or more, and in what
proportion, there are no means of determining. Camden assigns it to the Cornovii; Mr. Britton, in the 'Beauties of England and Wales,' to the Cornovii and the Wiganites, whom he identifies with the Jugantes or Jugantes, a people named only in one passage of Tacitus. *Annals, lib. xii.* 'Citius Jugantium,' of which the reading is disputed.

In the Roman division of Britain, Warwickshire appears to have been included in the province of Flavia Caesariensis.

Several Roman or other ancient roads cross the county or pass along its borders. The ancient Watling Street in its north-westward progress meets the border of the county on the east side near Hill Moreton, and runs along the north-eastern side of a manor of Middlemore, which, as its course, still north-westward, is wholly within the county to the passage of the Tame, between Whiteclere and Fazeley, where it enters staffordshire. While on the border it separates Warwickshire partly from Northamptonshire, but chiefly from leicestershire. The Fosse Way, another ancient road, enters the county on the south, and crossing first the detached portion of the county at Stronth-on-the-Fosse, and then the intervening portion of Worcsshire, enters the main part of the county at Holford-on-the-Stour, and runs down the county as far as Dunmore, Brinklow, and Wrotton-under-Fosse, to High Cross, where it intersects Watling Street and enters Leicestershire. Another road, designated in the Ordnance map the Roman road, enters the county at Baddesley Clinton, and runs north by west by Bagbury, Brinklow, and Dunmore, and intersects Watling Street and enters leicestershire. It diverges to the north-west, and in the map of Antient Britain is published by the Society for the Diffusion of Useful Knowledge, more correctly the 'Ryknield Way,' enters the county on the south-west side, and runs north by west by Bidford, Alcester, Studley, and Ipsey, into Worcsshire. It angles to the south-east, and after intersecting the Fosse near Alcester and Studley it is called 'The High Way.'

Some Roman towns and stations, in the county or on the border, may be identified. The Triportionum of Antoninus is fixed by Dugdale and Gale at Dove bridge, or Dove ford, on Watling Street, at the junction of the two counties of Worcs and Leicestershire, and Warwick, of Leicestershire, and Staffordshire. Roman coins turn up in the county or touches this border near Birmingham and near Sutton Coldfield; after which it enters staffordshire and intersects Watling Street at Exeterum, now Wall, near leicestershire. Between Alcester and Studley it is called 'The High Way.'

Some Roman towns and stations, in the county or on the border, may be identified. The Triportionum of Antoninus is fixed by Dugdale and Gale at Dove bridge, or Dove ford, on Watling Street, at the junction of the two counties of Worcs and Leicestershire, and Warwick, of Leicestershire, and Staffordshire. Roman coins turn up in the county or touches this border near Birmingham and near Sutton Coldfield; after which it enters staffordshire and intersects Watling Street at Exeterum, now Wall, near leicestershire. Between Alcester and Studley it is called 'The High Way.'

The Venues of the same writer is fixed by Camden, Stukeley, and others, at or near High Cross, where the Walling Street and the Fosse Road intersect. Camden has preserved a local tradition of an ancient most flourishing city, named Clecester, which had a senate of its own, and of which Cleybrook, about a mile off, was a part, and speaks of foundations of hewn stone built of bricks, into which the brooks were fitted; and the name Clecester is by the plough. The Mundaesium of the same writer is fixed at Maneceter or Manchester, near Atherstone. Here are evident remains of a Roman station; the ditch and valium being very perfect. Alcester may be identified with the Aulern of the 14th letter of Richard of Cireneester. Roman coins and medals of brass, gold, and silver, and antient bricks, have been found at Alcester. Probably the name may have belonged also to the river (Ampne) on which the town stands. It may be observed that Richard assigns this town to the Dobuni. Near Chester-ton, on the Fosse Way, is an encampment, evidently Roan, which is identified by Mr. Hatchard, the translator of Richard of Cireneester, with a station, the name of which is lost of Richard.

Roman coins or other antiquities have been found near Birmingham, Hampton-in-Arden, Willoughby near the Leam, on the eastern border of the county, and at Warwick; and a Roman pavement at Coventry. Mr. Reynolds mentions in his *Romish Remains* a Roman station at Holy Kirby, near Lutterworth and Coventry; but it is not marked in the Ordnance map. There are some earthworks at Brinklow, near Monk's Kirby, on the line of the Fosse, which Dugdale conjectured to be Roman.

In the earlier Saxon period Warwickshire formed part of the kingdom of Mercia. The southern part of the county, which has been all along included in the diocese of Worcester, appears to have been included in the subordinate kingdom of the Wiganites or Wiganites, as, in the *Bibliotheca Topographica Britanni," (1753. p. 123) 'provincia Hulceorum,' which was in existence as early as the middle or latter end of the seventh century. Notices of this subordinate principality or province continue down to the year 826. The treacherous death of the Mercian king Ethelbad, a.d. 807, is placed by the Saxon chronicle at Seccandune, apparently Seckington in Warwickshire, near Tamworth. Under King Alfred, Warwickshire came, with the rest of Mercia, to the west of Walling Street, into direct subjection to the West Saxon crown (about a.d. 868), and during part of the reign of Alfred and his son Edward the Elder was governed by the alderman Anbertheaer, and later by the lady Althouseaer or Ethelbeata, Alfred's daughter. During this and the subsequent reigns it was the scene of the war with the Danes or Northmen.

To this period of history, namely, a.d. 868, the third year of the reign of Athelstan, or the 6th of Edward, some of our early chroniclers assign the existence of the fabulous Guy, Earl of Warwick. According to the legend, Athelstan was at war with the Danes, who had penetrated to the neighbourhood of Winchester; and the Earl, depending on the course of the river Avon, has received by an English champion to be appointed, and Colbrand, who, though acting as champion of the Danes, is described as being an African, or Saracen, of gigantic size, whether the crown of England should be granted to Athelstan, or to Colbrand, point to a period subsequent to the Norman conquest, as in that in which the legend received its present form. Dr. Pegge has examined into the origin of the legend, in a paper contained in the fourth volume of the *Bibliotheca Topographica Britannica,* and has shown that no such legend existed before a.d. 1370, and that it was only in the time of the first Earl of Warwick, or the year 926, that the name of 'Uraswada, vicar of Warwick's, and Sheriff of Warwick's, it is probable that there were earls of Coventry, or perhaps Chester and Coventry, and one of these, i.e., the one who had acquired the government of Mercia, is connected another celebrated legend, that of the fair Godiva, his wife, who is said to have ridden naked through the city of Coventry. (Coven-

The legend is also sufficiently given by Leofric and Godiva are historical, not fabulous persons, and belong to the reign of Canute; and an ancient inscription accompanying a picture of the man, on a window of Trinity Church, Cambridge, is the only one that can be taken as evidence that the city owed some immunities to the lady's intercession. The inscription was—

*"I lenche, for the love of thur, Doe make Covento tolere*."

Warwickshire was ravaged by the Danes under Canute in the last year of the reign of Ethelred II., a.d. 1015.

In the civil war of Stephen and the empress Maud, Coventry, which was held by Bade, as well as Warwick, one of the supporters of the empress, was taken by the king's troops; and the attempt of the earl to retake it brought on
WAR

an engagement, in which the king was hurt, and the earl wounded and repulsed. This incident is given by Mr. Britton, in 'The Beauties of England and Wales'; but we cannot trace his authority, or fix the year of its occurrence. In the civil troubles of Henry III., after the defeat and death of Simon de Montfort, the castle of Kenilworth held out for the insurgents for seven months (a.d. 1266); and in the troubles of the reign of Edward II. the murder of Gaveston, the king's minion, took place at Blacklow Hill, near Warwick. He was taken from the castle of Warwick, now known as the Beacon, by the earl of Beauchamp, earl of Warwick (whom Gaveston had insultingly called 'the black dog of Arden'), and was beheaded by his order. The incident is commemorated by an ancient inscription in the rock near the summit of the hill:

P. GAVESTON, EARL OF CORNWALL, BEHEADED HERE.

1311.

In the war of the Roses the inhabitants of the county were divided between the two parties: the Warwick men, swayed by their earl, the celebrated 'king-maker,' were Yorkists; the men of Coventry, won by the frequent visits and favours of Henry VI. and his queen, Margaret of Anjou, were supporters of the house of Lancaster.

In the civil war of Charles I. the county generally embraced the cause of parliament, being especially influenced by the influence of Lord Broke. The first great battle of the war was fought at Edge Hill, in the southern part of the county (a.d. 1642). The king was near Banbury in Oxfordshire, where was a Parliamentary garrison, which he had ordered to be suppressed. His orders were carried out by an enthusiast, Sir John Lisle, and the town of Kineton, and the Royalists descended the hill to attack them. The battle was severe, but indecisive: the loss on both sides is commonly stated at 9,000; but the slain were probably near 10,000; the wounded may be made up the larger number. The Parliamentaryists retreated the next day to Warwick; while the king returned to Banbury, which he forced to surrender. The numbers engaged were stated in an account sent by some Parliamentary officers to the speaker of the House of Commons, and ordered by the house to be printed, at 10,000 on their own side, and from 14,000 to 22,000 (viz. 19,000 foot and 4000 horse) on that of the king. The king had marched through the county before the battle; and after his leaving Banbury, the townsmen acted his part and maintained the point, and conveyed it to Warwick Castle. They further showed their hostility by refusing to manufacture swords for the Royalists, while they readily supplied the opposite party. They were also known for their loyalty, and were known to的趋势 Prince Rupert, whom the king had ordered to open the communication between Oxford and York. The town was however taken by the prince early in April, 1643. A minister who acted as governor was killed, and part of the town burned. Warwick Castle, the principal post of the Parliamentarians, was attacked by the Royalists in the early part of the war, but without success.

The only incidents requiring notice in later times are the Birmingham riots. The first of these occurred in 1715, when several dissenting meeting-houses were destroyed or injured. The next occurred in 1719, when two dissenting meeting-houses and the dwellings of several dissenters, including that of Dr. Priestley, minister of 'the New Meeting' (one of those destroyed), were burned, and the doctor was obliged to fly for his life. The last great riot was connected with the Chartist agitation, and occurred in July, 1839, when several houses were destroyed. The population of the hundreds of 1715 were partly or wholly the result of religious bigotry; those of 1719 were partly or wholly the result of political; those of 1839 were political. The formation of the Great Western Union during the agitation of the Reform Bill, in 1831, led to some meetings of immense numbers of people, but was not attended by any breach of the peace.

STATISTICAL.

Population and Occupations.—As a manufacturing county, Warwickshire is the eighth in rank, a position which it maintained in 1811-21-31, standing in the last year between Northumberland and Staffordshire: the proportion of the manufacturing population was sixty per cent. In 1831, at which period there were 293848 workers employed, 114242 occupiers not employing labourers, and the number of agricultural labourers was 15,641. The remainder of the male population aged 20 and upwards was distributed in trade (including 11,575 employed in manufactures), 32,579 in retail trade, 32,401 as capitalists, bankers, and members of the professions; 10,268 non-agricultural labourers; 2446 domestic servants; other males aged 20 and upwards, 3729; and there were 13,089 female servants. The following details are from the Returns of 1831:—About 4500 men engaged in making ribbons, nearly one-half of them in the city of Coventry, upwards of 300 at Nuneaton, 900 at Foleshill, 300 at Acocks Green, 1200 at Dilston, 100 at Bow, 110 at Streetly, 100 at Scrivelsby, 100 at Chilton, 100 at Nuneaton, 100 at Swynnerton, 100 at Castle Hedingham, 100 at Southam, 100 at Walsall, and in many other places; and about 100 men are employed in weaving linen in various parts of the county. Watch-making has been successfully introduced at Coventry. Needles are made by 350 men, chiefly at Lapley, Studley, Alcester, and Sambourne; and at Kenilworth the manufacture of combs employs upwards of 160 men. But these and the smaller manufacturers of agricultural machines, rush-weavers, and others, are nothing in comparison with the activity displayed at Birmingham and Coventry.

The population of the county at the following decennial periods when the census was taken was as under:

It is estimated that in 1700 the population was 96,000: from 1801 to 1841 it increased 193,625, or 33 per cent. According to the last census the number of persons to a square mile is 464. The population, &c. of each hundred and borough in 1841 is shown in the following table, communicated by the commissioners of the Census, the returns not having yet been published:
In 1831 the number of inhabited houses was 68,233, inhabited by 72,357 families, and there were 702 houses building and 5982 uninhabited.

The expenditure for the year ending March 31, 1831, 1831-2, was as follows:—

The number of persons relieved in these unions during the quarter ending Lady-day, 1840, was 18,251 (1726 indoor, and 11,025 out-door), or 8 per cent. of the union population. There were 391 lunatics and idiots chargeable on the poor's rate in 1836, or 1 in 881; in England 1 in 1833. In 1836-7 there were 1861 bastard children chargeable on the poor's rate, or 1 in 293 of the whole population; in England 1 in 215. The number of illegitimate births in 1830 was 425, or 1 in 22; in England 1 in 20. The number affiliated in 1834-5 was 305, and 162 in 1835-6. In 1840 the proportion per cent. of persons married under 21 years of age was 10.4; in England and Wales 9.6, for the two sexes.

The annual value of real property assessed to the property tax in 1815 was £1,269,579; property assessed to occupiers, 906,925; and the profits of trades, professions, &c., were assessed at 685,582. In 1824-5 the central proportion of the various descriptions of property assessed was:—land, 50 parts; dwelling-houses, 31.3 parts; mills, factories, &c., 4.4 parts; manorial profits, &c. 1.9 parts.

The net rental or annual value of real property assessed to the poor's rate in 1841 was as follows:—

| On landed property | 713,300 |
| Dwelling-houses | 300,427 |
| All other kinds of property | 396,930 |
| **Total** | **1,609,747** |

In the above the total amount levied for poor-rates was £171,435, being a rate of 9s. 1d. in the pound on the annual value of real property assessed. Taking the total annual value of real property in the county in 1841, the rate per head was 4.3s. 1d. for each inhabitant; and dividing it by the number of acres was 1.7s. 6d. per acre, which is the same as for Lancashire, and is only exceeded by Middlesex and Worcestershire.

The county-rate levied at different periods, and the principal disbursements for the same periods, are shown in the following table:—

<table>

**Total**: £7,000

**Amount of rates levied**: £3,572.

**Expenditure in repaired highways**: £2,380.

**Law and other expenses**: £450.

**Total expenditure**: £3,292.

The number of turnpike trusts, in 1840, was 33; the income from tolls was £7,7292; parish compositions is £5,835; and total income, £26,850/. The total expenditure for the same year was £23,854. The best and mortgage debts amounted to £3,570. In 1840 the debt was equal to 3 years' revenue. For the whole of England the proportion of income to debt being 4:5 years: the proportion of unpaid interest to the total debt was, in Warwickshire, 8 per cent.; in England 12 per cent. The state of the county, as in 1841, is shown in the following table: the last column is an ordinary of the number of years which would be required for each trust to discharge its entire debts, taking the surplus revenue of the year 1840 as an annual surplus:—

Lending libraries of books were attached to 66 schools in 1833.

Sixteen Sunday-schools are returned from places where no other school existed. Sixty-six schools, containing 3,901 children, were both Sunday and day-schools. The number of boarding-schools is fifty-four, and the scholars are included in the above returns. The total number of children returned as attending Sunday and day-schools of all kinds is 60,273, which was above two-thirds of the total number of children in the county between the ages of 2 and 15.

WASHINGTON, the capital of the United States, is situated on the left bank of the Potomac, and on the right bank of the Anacostia, or Eastern Branch, about 38° 40' N. lat. and about 77° W. long. from Greenwich, according to Arrowsmith. By an act of Congress, passed in 1790, it was declared that the seat of government should be established at some place on the Potomac, and the district around Georgetown was ultimately ceded to the United States by Virginia and Maryland for this purpose. In 1792 the government advertised for plans of a capital and president's house. The name of Washington was

Vol. XXVIII. 10
ultimately bestowed upon the federal city; and, in conformity with the act of Congress alluded to, the west of government was transferred thither from Philadelphia in 1800. The president and other chief executive officers of the federal government have since resided at Washington: Congress meets there every year on the first Monday of December, and the Supreme Court of the United States holds its annual sessions, beginning on the second Monday of January.

Washington is separated from Georgetown by Rock Creek, over which there are several bridges, and from Alexandria by the Potomac, a bridge upwards of a mile in length. There are also several bridges over the Anacostia. This river has a sufficient depth of water for frigates to ascend, without being lightened, above the city, and, with its tributary, the Patuxent, which, drawing fourteen feet can come up to Potomac Bridge, whence to the mouth of the Tiber, a small stream which flows through the middle of the city, there are nine feet of water at ordinary high tides. A spacious canal unites the Potomac with the Patuxent, which is situated near the head of the tide-water navigation, and is connected with the interior by the Chesapeake and Ohio canal. The city is well supplied with water, and has in front (south) the Potomac, nearly a mile in width, and a range of heights in the rear (north), affording many fine sites.

The city was regularly laid out, according to the design of Major L'Enfant, but only a small part of the ground embraced within the plan is built upon. The Capitol is the central site; a large square, nearly a mile wide, named after the states of the Union, are to extend from it to the most important public buildings, or the places which offer the finest prospects. These avenues intersect diagonally square blocks formed by streets crossing each other at right angles. The streets of the capital are designated by the letters of the alphabet, A, north, A, south, &c.; those east and west of it are numbered, 1st east, 1st east street, 1st street west, &c. The streets are from 70 to 200 feet wide. The effect of the partial filling up the magnificent plan of the city was thus described by Basil Hall in 1827—‘This singular capital is so much scattered, that scarcely any of the ordinary appearances of a city strike the eye. Here and there ranges of buildings are starting up, but by far the greater number of the houses are detached from one another. The streets, where streets there are, have been made so unusually wide, that the connection is quite loose; and the whole affair, to use the quaint simile of a friend at Washington, looks as if some giant had been in a box of his children at random over the ground.’ Mrs. Trollope, who will scarcely be suspected of undue partiality, and who visited Washington much about the same time, speaks more eulogistically of its appearance,—‘The whole aspect of Washington, light, graceful, and spacious, is full of the best ideas of art; and the various departments of the government are each placed in its respective situation, the Navy-yard and arsenal immediately to the north of it, are situated on the Anacostia, just below the low bridge which spans the Potomac and connects the Mary-land and Virginia shores. The Navy-yard are attached marine barracks, and to the arsenal public manufactories of arms and military stores. The river, on arriving at Washington, makes a beautiful sweep, forming a bay, on which the city stands. The navy-yard and arsenal fravc the curve.’ The representatives' chamber, at the south wing, is also a semicircle: it is 75 feet long and 60 feet high. The dome is supported by twenty-six columns and pilasters of Potomac marble. A colossal statue of Liberty and a statue of History are the principal ornaments of the hall. The Senate chamber, and nearly of the same form and dimensions, is the hall in which the sessions of the Supreme Court are held. Below the representatives' chamber are committee-rooms and other places of business.

The government's Bank is on the hill at the opposite extremity of Pennsylvania avenue from the Capitol. It is a handsome building two stories high, with a lofty basement. 190 feet long by 86 wide. In convenient proximity to the mansion are four simple and commodious brick houses which contain offices and establishments of the postal departments. The General Post-Office contains also the Patent-Office. Ample areas are left round each, whose shrubs and grass refresh the eye. The Patent-Office contains models of all the mechanical inventions produced by the genius of the country, and is visited by persons from remote districts, who had been spurred by necessity to invent substitutes for human labour, and brought them to Washington for patents. At the secretary of state's office are shown by autographs of the potomac marble. There are or have been in alliance with the Union, and the presents made by foreign courts to American ambassadors. At the office for Indian affairs are the portraits of all chiefs who have from time to time come to negotiate with the president. This quarter of the city is almost entirely given to private houses, most of which are occupied by the foreign ministers.

The navy-yard, and the arsenal immediately to the north of it, are situated on the Anacostia, just below the low bridge which spans the Potomac and connects the Maryland and Virginia shores. The navy-yard and arsenal are attached marine barracks, and to the arsenal public manufactories of arms and military stores. The river, on arriving at Washington, makes a beautiful sweep, forming a bay, on which the city stands. The navy-yard and arsenal fravc the curve.

Near the arsenal is a penitentiary. There are besides in Washington a city-hall, four market-houses, twenty churches, an orphan asylum, almshouse, &c. Columbian College, which was incorporated by Congress in 1821, is a grand institution, and has the honour of containing the oldest college in the Union, and a library of 4200 volumes. A medical department is attached to this college. There is also a college under the direction of Roman Catholics at Georgetown, which has nineteen instructors and a library of 22,000 volumes.

The census of 1840 gives 23,264 as the total inhabitants of Washington. The total inhabitants of the federal district of Columbia was 43,712; of whom 7312 resided in Georgetown, 8459 in Alexandria, and 4077 in the city of Washington. 28 are said to have been employed in agriculture, 103 in commerce, 886 in manufactures and trades; 45 were seen of the long voyage, 25 navigators of lakes, canals, and rivers, and 63 mechanics and the learned professions in two colleges in the vicinity of Washington had 284 students in 1840. There were in the city 12 academies and grammar-schools, with 609 scholars; 9 primary and common schools, with 167 scholars; and 213 scholars were
supported at the public expense. There were in the city 383 white persons upwards of 20 years of age, who could neither read nor write. There were 640 male and 1064 female slaves; 1949 males and 2868 female free persons of colour; 8025 male and 8647 female white persons.

The population of Washington consists of members of the legislature and of the executive departments of state and of foreign diplomats, with the addition of such professional, trade, and domestic workers as are required to minister to their comfort. The tone of society, as might be anticipated from this circumstance, differs considerably from that which prevails in other parts of the Union. Owing to the influence of the example left by the foreign diplomats, it approaches more nearly in some respects to that of Europe. On the other hand, the elective character of the legislature and executive government occasions an ample supply of specimens of all the peculiarities of practice and conduct, which are current in the United States. Washington. The fashionable amusements are as in Europe—balls, soirees, dinner parties, and promenades. Washington does not support a permanent dramatic company. It is said that there is a good deal of high play. The sociality of both is ample. The finer arts are less cultivated, though the Capitol affords a fair promise for the future.

(The American Almanac; The Sixth Census of the Inhabitants of the United States; Encyclopaedia Americana; Memoirs of降温 for Persons; Travels of Captain Hall, Mrs. Trollope, Mr. Dickens, and the Author of 'Cyril Thornton.')

WASHINGTON, GORGE, was born in Westmoreland county, Virginia, on the 22d of February, 1732. The first of the Washington family, and the eldest son of the eldest and a daughter. The mother of George Washington survived to see her son president. Augustine Washington left all his children in a state of comparative indepen-...
and establish a uniform system of manoeuvres and discipline.

In 1753 the French in Canada pushed troops across the lakes, and at the same time bodies of armed men ascended from New Orleans to form a junction with them, and establish themselves on the upper waters of the Ohio. Governor Dinwiddie resolved to send a commissioner to confer with the French officer in command, and inquire by what authority he occupied a territory claimed by the British. This charge required a man of discretion, accustomed to travel in the woods, and familiar with Indian manners. Washington was selected, not withstand his own weakness of the post.

He set out from Williamsburg on the 31st of October, 1753, and returned on the 10th of January, 1754. He discovered that a permanent settlement was contemplated by the French within the British territory; and, after making the interview of the governor, he contrived to bring back with him a plan of their fort on a branch of French Creek, 15 miles south of Lake Erie, and an accurate description of its form, size, construction, cannon, and barracks.

The military establishment of the colony was increased to six companies: Colonel Fry, an Englishman of scientific acquirements and gentlemanly manners, was placed at the head of them, and Washington was appointed second in command. His first campaign was a tryout, 'for the sake of the soldier' for him, and he did it with three small companies to occupy the outposts of the Ohio, in front of a superior French force, and unsupplied by his commanding officer. Relying upon his own resources and the friendship of the Indians, Washington pushed into the Ohio Valley on the 27th of July, 1754, and defeated a detachment of the French army under M. de Jumonville, who fell in the action. Soon after Colonel Fry died suddenly, and the chief command devolved upon Washington. Inns, the commander of the North Carolina troops, was elected by the assembly, and a new commander never took the field. An ill-timed parsimony had occasioned disgust among the soldiers, but Washington remained unconquered. Anticipating that a strong detachment would be sent against him from Fort Duquesne, he left at once to join the assembly, and entrenched himself on the Great Meadows. The advance of the French in force obliged him to retreat, but this operation he performed in a manner that elicited a vote of thanks from the House of Burgesses.

In 1755 Colonel Washington acceded to the request of General Braddock to take part in the campaign as one of his military family, retaining his former rank. When privately consulted by Braddock, 'I urged him,' wrote Washington, 'I advised him to push it. I don't know if he ever did it with a small but chosen band, with such artillery and light stores as were necessary, leaving the heavy artillery and baggage to follow with the rear division by slow and easy marches.' This advice prevailed. Washington in his turn had to leave, and was divided by the division in which he was only able to join the rear division on the evening before the battle of the Monongahela. In that fatal affair he exposed himself with the most reckless bravery, and when the soldiers were finally put to the rout, hastened to the rear division to order up horses and wagons for the wounded. The panic-struck army dispersed on all sides, and Washington retired to Mount Vernon, which had now, by the death of his brother, become his own property. His bravery was universally admitted, and it was said that latterly his prudent counsels had been disregarded.

In the autumn of the same year he was appointed to reorganize the provincial troops. He retained the command of the troops until 1758. The tardiness and irresolution of provincial assemblies and governors confined him to act during much of this time upon the defensive, but to the necessity he made up his mind and, his no less for the matter of the army, but himself before him. The Virginia troops remained on the footing of militia, and Washington had ample opportunities to convince himself of the utter worthlessness of a militia in time of war: in the beginning of the war, Washington had prevented the Virginia troops from joining the expedition. The Virginia troops had been called out, but they were not called upon to perform any service of importance. The Virginia troops had been called out, but they were not called upon to perform any service of importance. He was appointed an officer of the Virginia troops, but he refused to serve. principles both of the war of detail and the war of large masses: On the other hand, his punctual habits of business, his familiarity with the details both of agriculture and commerce, and the experience he had acquired as trustee, arbitrator, and member of the House of Burgesses, were so many preparatory studies for the duties of the statesman. He commenced his great task of first liberating and then governing a nation, with all the advantages of this vast country. Beyond the sea his labors were directed to the physical vigour is undiminished and the intellect fully ripe. He persevered in it, with a brief interval of repose, for upwards of 20 years, with almost uniform success, and with an exemption from the faults of great leaders unparalleled among his countrymen. Washington was elected commander-in-chief on the 15th of June, 1775; he resigned his commission into the hands of the president of Congress on the 23rd of December, 1783. A few days after his appointment he left Philadelphia to join the army at Cambridge, Massachusetts. The particular of the battle of Bunker's Hill reached him at New York, and increased his anxiety to hasten forward. He arrived at Cambridge on the 2nd of July, and assumed the command on the 29th, at which time the army consisted of about 17,000 men, collected on the spur of the moment, occupying a range of posts disproportioned to their numbers, and almost under the guns of the enemy. There were few stores, no military chest, and no adequate funds. Washington was received with astonishment that there was not powder enough in the camp to supply nine cartridges for each man. There was much discontent among the general officers on account of the manner in which the appointment was made by Congress; the subordinate officers and privates formed themselves into parties, referring their complaints to Congress. Washington proceeded to mature his plans. The army was formed into six brigades of six regiments each. The commander-in-chief, colonel, were, whenever it was practicable, brought together and placed under a commander from that colony. All the officers were commissioned anew by Congress, and by degrees a continental army was formed. He kept up an uninterrupted correspondence with Congress, which, though tardily, adopted all his important suggestions. He corresponded also with the heads of the provincial governments, and subsequently with the governors and legislatures of the several states. He thus became not only the creator of the volunteer army, but the invariable leader of the army, and the machinist between it and the numerous and complicated depositaries of power in the United States.

The army was at first distributed into three grand divisions of two brigades each: the division forming the left was stationed near the Schuylkill, under General Lee; the centre division at Cambridge, under Major-General Putnam; the right wing at Roxbury, under Major-General Ward. The head-quarters of the commander-in-chief were with the last named and the place was fitted up with little alteration till far in January, 1776. During that interval the regular army, by the departure of many of whose term of enlistment had expired, and in consequence of the slow progress of the recruiting, was reduced to 2500 men, to whom were added 10,000 provincials, who were to remain only till the middle of January. 'Search the volumes of history through,' Washington wrote at this time, 'and I much question whether a case similar to ours is to be found, namely, to maintain a post, and to maintain it with a body of men who were together without powder, and then to have our army disbanded and another to be raised within the same distance of a reinforced enemy.' During this time he detached 1100 men, under Arnold (14th September), in the direction of the Schuylkill and spring hills, and from the New England ports. Occasional cannonades and skirmishes took place at the advanced posts. But no decisive blow could be hazarded, and the patience and forbearance of the commander-in-chief were severely tried by the cabals of the officers, the undisciplined habits of the men, and the pragmatical conduct of the civil authorities.

Towards the end of December, 1775, General Howe, who had succeeded Clinton as commander-in-chief, was closing in to Boston harbour for some secret enterprise. General Lee was despatched to place New York in a state of defence, but the expedition proved to be destined against North Carolina. Washington became impatient to attack Boston, but was twice overruled by a council of war—on the 16th of January and on the 10th of February, 1776. At last, on the 15th of March, the Americans took possession of Dorchester Heights; and on the 17th the British evacuated Boston. As soon as the British fleet had put to sea, Washington set out for New York, before the enemy returned to the camp. He perceived the physical vigour is undiminished and the intellect fully ripe. It was the 29th of March when Howe's forces appeared off Sandy Hook; but the deficient means at Washington's command, and the strength of the royalist party in New York, had materially impeded his preparations for the defence. The immediate loss of some of Washington's officers enabled the enemy to gain the possession of Long Island on the 27th of August; and the weakness of his army and fears of the soldiers obliged him in succession to evacuate New York, cross the Hudson, and retreat behind the Delaware. Congress at last saw the necessity of raising a regular army of men enlisted for a longer period than a year, and of investing Washington with dictatorial powers. Thus strengthened he remodelled his troops, recrossed the Delaware on the night of the 29th of December, 1776, and invested New York with garrison and fortifications. The American forces had received a supply of arms from France, but he was still uncertain of his new lieves. He was also kept in suspense by the real designs of the British commander. It was only an object to the English the command of the Hudson, keep up the communication between New York and Canada, and isolate the eastern from the western states. But there was also danger in leaving Philadelphia exposed, and as her French spruce, with the few of their troops. The British took possession of Philadelphia after the battle. On the 16th of December Washington began to construct a fortified encampment at Valley Forge. He was at this time harassed by Debts among the general officers, Benno the, and Mifflin, aided by a small party in Congress, conspired to have him removed from the command. The good sense of the majority in Congress frustrated the plot, and the attachment of the soldiers, heightened by the enthusiasm with which they had followed the British flight into Washington's scale, kept the army in good temper. The winter was however a trying one for the troops. Owing to the derangement of the commissariat, the men were in a bad state of health, and this was due to the bad times even with food. With the experience of three campaigns, Washington now set himself to plan an entire remodelling of the army. He invited the general officers to state their sentiments on the subject in writing. Congress at the same time appointed a commission to visit the camp, which remained there three months. With great difficulty the commander-in-chief wrung from Congress the promise of half-pay for seven years for the officers, and a gratuity of 80 dollars for each non-commissioned officer and private for the duration of the war. The ratification of the treaty with France was celebrated in the camp with great solemnity on the 8th of May. The British in Philadelphia, though only twenty miles distant from the American camp, allowed the French ships without interference to sail up to within sight of the war. The ratification of the treaty with France was celebrated in the camp with great solemnity on the 8th of May. The British in Philadelphia, though only twenty miles distant from the American camp, allowed the French ships without interference to sail up to within sight of the war.
and four frigates, arrived about the same time off Sandy Hook. The American army was engaged for four months in arrangements for the defence of New England; during which interval the English laid New Jersey waste. Washington in December retired into winter-quarters—distributing his troops in line of cantonments around New York extending from Long Island Sound to the Delaware.

During the whole of 1779 Washington retained his position in the highlands of the Hudson, and remained on the defensive. An expedition fitted out to chastise the Indians was successful. The British, in a number, moved toward the Jerseys, but Washington covered New Jersey. Baron Steuben effected an improvement in the discipline and evolutions of the American army.

Lafayette returned from a visit to France before the end of April. The intelligence that the French government had fitted out an armament of land and naval forces which might soon be expected in the United States. Rochambeau arrived at Newport, Rhode Island, on the 10th of July. A plan of combined operations against the British was recommended by the states to the French commanders. The naval superiority of the English however prevented anything being done, and the year wore away unmarked by any incidents, except the treason of Arnold and the execution of André.

Congress, yonder, the English were defeated and Rochambeau and his army returned to France. Washington was in pain at the news of the retreat of the French, and he wrote to the American commanders that all troops to be raised in future should be enlisted to serve during the war, and that all officers who continued in service to the end of the war should be entitled to half pay for life. The army went into winter-quarters towards the end of October at the Jersey line near Newburgh, the New Jersey regiments at Pampton, and the eastern troops in the Highlands, while the head-quarters were at New Windsor, on the Hudson.

The year 1780 opened with a mutiny in the Pennsylvania and New Jersey regiments, instigated by the promptitude and self-possession of Washington. He was now strengthened not only by a French auxiliary army, but by liberal supplies from France. The main source of his weakness was the want of a civil government to support him. The Congress, which made war, declared independence, formed treaties of alliance, sent members to foreign courts, emitted paper currency, and pledged the credit of all the states for its redemption. "Ventured," says Mr. Sparks, "to raise troops, levied taxes, clothe and feed their naked and starving soldiers, Tilly with the French fleet entered the Chesapeake in February, but returned without injuring Arnold's squadron. Lafayette, whom Washington had despatched at the same time, was received in Virginia, and Cornwallis, who had advanced from North Carolina, in cheek. Washington had repeated interviews with the French commanders to concert a plan of campaign. On the 4th of July he encamped near Dobb's Ferry, and was joined on the 8th by the French army. Armour, at the request of Rochambeau, was sent to New York, and a letter intimating that De Grasse, who commanded the French fleet, could not remain on the coast after October, decided him to relinquish the siege of New York and advance into Virginia with all the French troops and as many of the American as could be spared from the defence of the posts on the Hudson and in the Highlands. Washington and Rochambeau reached Lafayette's head-quarters at Williamsburg in Virginia, on the 14th of September, and previously sent the Chesapeake and landed 9000 men from the West Indies, from the Lafayette. Cornwallis took possession of York Town and Gloucester on the opposite side of York river in Virginia. The American and French generals advanced from Williamsburg to York Town in September and October. Cornwallis proposed a cessation of hostilities on the 17th of October, and signed the articles of capitulation on the 19th. Two thousand continental troops were marched to reinforce General Greene in the southern army. Washington remained at Williamsburg; the American forces were marched into winter-cantongments in New Jersey and on the Hudson.

Hitherto Washington had to struggle against the apathy engendered by fear; now he had to check the remainder which sprung from an over-estimate of success. 'Whatever,' he said, 'may be the policy of European courts during this winter, their negotiations will prove too precocious a dependence for us to trust to. Our wisdom should dictate a serious preparation for war, and, in that state, we shall find ourselves in a situation secure against every event.' Congress concurred in these sentiments. The commander-in-chief addressed circular letters to the governors of all the states, urging them to make strenuous exertions for carrying on the war. In the middle of April he joined the army and established his head-quarters at Newburgh. Little progress was made by the states in filling up their quotas, and on the 8th of May he was obliged to remonstrate with them in energetic terms. Great discontent, occasioned in the camp and among the soldiers, he had experienced, and a wish spread that Washington should establish a monarchy in the United States. In the meantime negotiations for peace were commenced, the French army withdrawn, and the American army, after an inconsiderable remission in its operations, was dismissed, and the sending of troops was suspended in an angry correspondence between the officers of the army and Congress. An address from Washington (18th March, 1783) was required to restore the good temper of the officers. Having pacified them, he became their advocate and securing their promises to the demand. On the 8th of June he addressed his last official communication, a circular letter to the governors of the states, urging upon them— an indissoluble union of the states; regard to public justice; the adoption of a proper military establishment; and the observation of the laws and the execution of the laws of the different states. On the 25th of November the British evacuated New York. On the 4th of December Washington took a solemn farewell of the officers of the army. And on the 23rd of December he resigned his commission to the head of the new executive department.
of war. Randolph had the post of attorney-general. The appointments to the supreme court cost him much anxious study and work, and his health, after making those appointments, undertook a tour through the eastern states, and returned to be present at the opening of Congress in January, 1790.

In his opening speech he recommended to the attention of the officers a system of laws for naturalizing foreigners; a uniform system of currency, weights, and measures; the encouragement of agriculture, commerce, and manufactures; the promotion of science and literature; and an effective system for the support of schools. Knox and Randolph advocated the establishment and vehement debates. At last, Hamilton's plan for funding all the domestic debts was carried by a small majority in both Houses of Congress. The president supported the sentiments of the president pro tempore in Congress, but he approved the act for funding the public debt, and was from conviction a decided friend to the measure. The foreign relations of the country, though not complicated, were in an unsettled condition. Washington despatched Gouverneur Morris as a private agent to ascertain the views and intentions of the British ministers. He reluctantly commenced an Indian war, which lasted during the greater part of his administration. For the first year of his presidential term, however, he was chiefly engaged in proposing the national position of the United States in the system of nations.

The second session of Congress was mainly occupied with debates on the erection of a national bank. The two great sections of public opinion, which have under different names often operated commerce, had in some measure taken up their respective grounds on the question of funding the debt. Their organized hostility became more apparent in the debates on the project of a national bank. Both parties were represented in the cabinet: Knox and Hamilton advocated the establishment of the bank; Jefferson and Randolph denounced it as unconstitutional. The contest ended in the establishment of a bank, with a capital of ten millions of dollars, of which eight millions were to be held by individuals, and the rest by the United States. A plan, with some modifications, passed the House of Representatives, but was rejected in the Senate by the casting vote of the vice-president.

A circumstance insignificant in itself increased the bitterness of the contest out of doors. Democratic societies had been formed on the model of the Jacobins in the twelfth of Fructidor of France. Washington regarded them with perhaps exaggerated alarm, and the unmeasured expression of his sentiments on this head subjected him to a share in the attacks made upon the president's house of undue fondness for England and English institutions.

Advices from the American minister in London represented that the British cabinet was disposed to settle the differences between the countries amicably. Washington nominated Mr. Jefferson to the Secretary of State in Great Britain. The nomination, though strenuously opposed by the democratic party, was confirmed in the Senate by a majority of ten to one. The treaty negotiated by Jay was received at the seat of government in March, 1795. The treaty was soon after the ratification of the British cabinet summoned the Senate to meet in June to ratify it. The treaty was ratified. Before the treaty was signed by the president it was surreptitiously published. It was vehemently condemned, and public meetings against it were held to incite the execrations against the president. President nevertheless signed the treaty on the 18th of August.

When Congress met in March, 1796, a resolution was carried by a large majority in the House of Representatives, requesting the president to lay before the House all documents relating to the negotiations. Washington declined to furnish the papers; a vehement debate ensued; but in the end the majority hostile to the treaty yielded to the exigency of the case, and united in passing laws for its fulfilment.

The two houses of Congress met again in December. Washington had published on the 15th of September his farewell address to the United States. He now delivered his last speech. Congress, in consequence of the letter from Mr. Jefferson, the federalist candidate, had the highest number of votes; Jefferson, the democratic candidate, was consequently declared vice-president, the next.
Washington's commanding character and isolation from party had preserved this degree of strength to the holders of his own political views; his successor Adams being a partyman, by his injudicious if deliberate conduct of himself which the federalists turned the scale in favour of the democrats. Washington was present as a spectator at the installation of his successor, and immediately afterwards returned to Mount Vernon.

He survived till the 14th of December, 1796, but, except when summoned in May, 1798, to take the command of the provincial army on the prospect of a war with France, did not again engage in public business.

Washington had a sense of simple and substantial greatness. His passions were vehement, but concentrated, and thoroughly under control. An irresistible strength of will was the secret of his power. Luckily for his country this strong will was combined with a singularly well-balanced mind, with much sagacity, much benevolence, much love of justice. Without possessing a spark of what may be called genius, Washington was endowed with a rare quickness of perception and soundness of judgment, and an eager desire of knowledge. His extremely methodical habits, which in a person engaged in less important matters would almost have appeared ridiculous, enabled him to find time for everything, and were linked with a talent for organization. During the War of Independence he was the defensive force of America: wanting him, it would almost be as if the design of the mass movement had resolved itself into its elements. To place Washington as a warrior on the footing of the Cæsars, Napoléons, and Frederics, would be absurd. He lost more battles than he gained, and he lost them from defective strategy. But he knew the art of victory and kept up a spirit under more adverse circumstances than any other general ever did. His services as a statesman were pretty similar in kind. He upheld the organization of the American state during the first eight years of its existence, amid the storms of popular controversy, and gave it the stamp of solidity. No other American but himself could have done this: for all the American leaders, he was the only one of whom men felt that he differed from themselves. The rest were soldiers or civilians, federalists or democrats, but he was an American. Hence felt and blended with affection for his kindly qualities, and except for a brief period towards the close of his second presidential term, there has been but one sentiment entertained towards him throughout the Union—that of reverence, respect, affection, and confidence. Of those rare forms of great moral greatness followed without his appearing to seek for it.

Jefferson's sketch of Washington's character, quoted by Tucker, with the remark that it 'has every appearance of candour, as it praises without extravagance, qualifies its commendations, and arranges blame in the closest possible manner,' is valuable as coming from one who long enjoyed opportunities of close personal observation, was a shrewd judge of character, and the leader of the party opposed to Washington's general policy. It is as follows:

'His mind was great and powerful, without being of the very first order; his penetration strong, though not so acute as that of a Newton, Bacon, or Locke, and, as far as he saw, no judgment was ever sounder. It was slow in operation, clouded by imagination or imagination, but sure in conclusion. Hence the common remark of his officers, of the advantage he derived from counsels of war, where hearing all suggestions, he selected whatever was best in any plan generally ever planned his battles more judiciously. But he determined during the course of action, if any member of his plan was dislocated by sudden circumstances, he was slow in a re-adjustment. The consequence was, that he often failed in the field, and rarely gained a victory, as at Boston and York. He was incapable of fear, meeting objects with the most unconcern. Perhaps the strongest feature in his character was prudence, never acting until every circumstance, every consideration was maturely weighed; refining, if he saw a doubt, but when once decided, going through with his purpose, whatever obstacles opposed. His integrity was the most pure, his justice the most inflexible I have ever known; no motives of interest or consanguinity, of friendship or hatred, being able to bias his decision. He was indeed in every sense of the word a wise, a good, and a great man. His temper was naturally irritable and high-toned; but reflection and resolution had obtained a firm and habitual ascendency over it. If ever however it broke its bonds, he was not only generous, but very, brave, honourable, but exact; liberality never expected what promised utility; but frowning and unfurling on all visionary projects, and all unworthy calls on his charity. His heart was not warm in its affections; but he was carefully cultivated every mean and every sentiment of him the sole and sole esteem proportionate to it. His person was fine, as exactly what one would wish; his deportment easy, stately, and noble; the best horseman of his age, and the most graceful figure that could be seen on horseback. Although he was of the circle of his father than the might be unversed in life and love, with safety, he took a free share in conversation, his colloquial talents were not above mediocrity, possessing no copiousness of ideas nor fluency of words. In public, when called on for a sudden opinion, he was unreserved, short, and embarrassed. Yet he wrote clearly, sufficiently, in an easy and correct style. This he had acquired by conversation with the world, for his education was merely reading, writing, and common arithmetic, to which he added surveying. His time was employed in serious, reading little, and that only in agriculture and English history. His correspondence became necessarily extensive, and with journalising his agricultural proceedings occupied most of his leisure hours within doors. On the whole his character was in its mass perfect, in nothing wanting except in freedom of speech; in this it was without virtue that never did nature and fortune combine more perfectly to make a man great, and to place him in the same constellation with whatever worthies have merited from man an everlasting remembrance. For his was the singular and very uncommon instance of a man who succeeded successfully through an arduous war for the establishment of its independence; of conducting its councils through the birth of a government new in its forms and principles, until it had settled down into a quiet and orderly train; and of subduing the risings of his countrymen with a firmness and a constancy never equalled in his career, civil and military, of which the history of the world furnishes no other example.'

(Jared Sparks, Life of Washington; Judge Marshall, Life of Washington; George Tucker, Life of Thomas Jefferson; Writings of George Washington, edited by Jared Sparks.)

WASHITA, or ONASHITA. [Mississippi River.]

WASP, the name familiarly applied in English to insects of the genus Vespa, of which there are several native species. In America, Vespa furtiva is common. France, Britain, and America have each a ground-wasp, as also is the Vespa rufa, a rare species making smaller nests and associated in less populous societies. Of tree-wasps we have Vespa holsatica of Linnaeus, which is the Vespa Anglica of Leach, and the Vespa germanica of the last-named author. A new British species has been described under the name of Vespa borealis, by Mr. Frederick Smith, in an interesting paper on British wasps, in the 'Zoologist' for June, 1843. It lives in fir-woods in Yorkshire and in the north of Scotland.

Wasps live in societies, composed of females, males, and neuters or workers, which are essentially females, but have the reproductive organs undeveloped or passive. The females are usually largest, but of them there are two sorts—one containing two large eggs which produce two sexes, while the other is about the same size, and lays only male eggs. The larger kind are produced later than the workers, and come forth to be queens and to found new colonies in the following spring. The queen is then started to become a new state, the queen-mother is at first an outcast and alone. Industry effects her greatness. With instinctive ambition, ere her subjects are born, she lays the foundations of her kingdom, building the first houses herself. She then gives birth to her only daughter, who feeds and nurses without assistance. 'At length,' to quote the animated description of Kirby and Spence, 'she receives the reward of her perseverance and labour, and is crowned by being a solitary, unconnected individual, in the autumn.'
number of her children and subjects, and in the edifice
they inhabit—the number of cells in a wasp
sometimes amounting to more than 16,000, almost all of
which contain either an egg, a grub, or a pupa, and
the cell serving for three generations in a year; which, after
making every allowance for failures and casualties, will
give a population of at least 80,000. Even at this time,
when there are no aerials of conductors, the in-
dustry of this creature does not cease, but she continues to
set an example of diligence to the rest of the community.
If, by any accident, before the other females are hatched,
the queen-mother perishes, the neuters cease their labours,
and the community perishes with her.

The community of wasps and its nest are called a
vespary. There are several hundred females in a large ves-
parly, few of which survive the winter. The survivors fly
about in spring actively engaged in preparations for their
further life and the rearing of the next generation. In
their youth they emerge from the pupas towards the end
of August, and at the same time with the males. They pair
in September and October. The males are about equal
in number with the females. Their habits are industrious,
and they are sociable even to a degree that makes them
faithful servants of the commonwealth of which they are
members. The food they collect is shared among all
with impartial justice. The worker bringing home his
pupae, perches on the top of the nest amid his
fellow-workers; the males of wasps have no digested
collected, fairly distributes them. When not occupied on
foraging expeditions, the neuters are employed in the
enlargement and repair of the nest. Celerity and order pre-
val in all their operations. Each of the masons has his
allotted space, an inch or an inch and a half in extent,
wherewith he conducts his plastering occupation, his mouth
serving as a hod, carrying a ball of ligneous fibre, pre-
noviously torn by his powerful jaws from gateposts, wood-
blocks, and neighbouring trees. This fibre, knitted to-
gether, builds up a frame of wood, or a skeleton, on
which are constructed the combs, each made up of a
number of hexagonal cells opening downwards. The
outside of the whole nest is covered with foliaceous layers.
It is probable that the substance of the comb is made from
the gelatinous American species, namely, by him from a fresh
mixture of sound and decayed. The nest of tree-wasps are
finest and closest in texture, which is necessary, since
they are so much more exposed to the vicissitudes of the
weather than those which are buried in the ground. Some
foresters have noticed that their nests of a solid and thick
pasteboard, impermeable to the rain; others diversify the
outside of their habitations with conical knobs of various
shapes and sizes, supposed to be defences against their
enemies. A person who entered within a few feet of the
entrance from the wet, the entrance-hall being so twisted as
to prevent the invasion of hostile insects. The cells of the
comb of the common European wasp are brown, and
coarse in texture; but where the larvae have spun their
combs on wood, they are of a fine and soft appearance.

Many years ago Azara stated that there are wasps in
South America which collect honey. This was at first
doubtful, but is now confirmed by M. Auguste St.
Hilare, who found near the river Uruguay nests of a wasp
constructed like those of the European species, containing
honey of an agreeable taste, but poisonous quality; and
Mr. Adam White has recently given a detailed description
of a species from the eastern States, which stores up honey in
tits comb. (See "Annals of Natural History," for June, 1841.) In our own
country the wasps are fond of honey, but obtain it by
plundering the bee-hives, which, being the more powerful
insects, they are enabled to do by main force. The bees,
suffering from the cold in the mornings and evenings of
the latter end of the season, retire into the snugger and
warmer recesses of the hive among the honeycomb, when the
wasps, not so delicate in constitution, take advantage of the unguarded entrances of the bee-hive and enter to levy
tribute. Rummaging up the inside, they gather the honey, and carry away all they can. Hornets, still more
impatient, attack the bees when laden with their treasures
in going homewards, and carry them off prisoners, to
which no quarter is shown. Both bees and wasps play great sacriency when the body of the captive is too
heavy for their strength, by cutting off the head and limbs
to lighten the weight.

Wasps have sentinel places at the entrances of their
nest to give an alarm in case of danger. If these guards
are seized and destroyed, the rest do not attack. Mr.
Knight observed that if a nest of wasps be approached
without alarming the inhabitants, and all communication
be suddenly cut off between those out of the nest and those
within it, no protest of the inhabitants of the former to defend
it and themselves. But if one escapes from within, it
comes out angrily, as if commissioned to avenge the wrong,
and will sacrifice its life in defence of the community.
Mr. Smith, in the paper referred to, has made some
interesting observations on the increase of the wasps. He
writes: 'I was curious to try the experiment, but in several instances I could not detect any wasp
apparently on duty; however, in Plumstead wood, last summer, I saw a wasp at the entrance of a nest, which
flew at me, and then going a little farther in. This I thought very like the actions of a sentinel, so
I got a piece of paling, and, watching my opportunity,
suddenly pushed it in an oblique direction into the ground,
so as to cut off all communication by that way. The sentin-
el flew at me, but I captured him in a little time, as
he was most perseveringly charging and recharging upon
me, and seemed determined to conquer or to die: the
latter was his fate. When I returned to the nest, a num-
ber of them, by the time I reached it, had declined to let me approach unheeded, but flew around me
to all appearance intent on revenge. Perhaps the sup-
posed sentinel, in his wide circulations, while attacking
me, had communicated the alarm.'

For full accounts of the habits of these interesting in-
sects, consult the writings of Rauzumur, and Kirby and
Spence's 'Introduction to Entomology.' For the charac-
ters of the family to which they belong, see VESPIDAE.

WASSELINNE, [Renn Bas.]

WASTE (from the French, ") is the committing of any
improper spoil or destruction in houses, lands, &c.,
by tenants for life or for years, to the damage of the heir
or of the person entitled in reversion or remainder. Waste
is either voluntary, which is an act of commission, or
pernicious, which is a state of condition or omission only.

Voluntary Waste chiefly consists—

1. In felling timber-trees. This kind of voluntary waste
is where a tenant takes good timber coming within the
description so to cut it off, especially for consumption by
himself, not as the former it was, and if it be larger than the former it is still waste, on the
ground that the new house will be more chargeable to
the fessor to repair. (1 Inst. 53, 4.)

2. In pulling down houses. If a lessee raises a house
and builds a new one not so large as the former it is
waste, and if it be larger than the former it is still waste,
on the ground that the new house will be more chargeable to
the fessor to repair. (1 Inst. 53, 4.) But the rule
which establishes that whatever is once annexed to the
freehold becomes part of it, and cannot be removed with
out doing waste, has been relaxed both as between land

Vol. XVII.—P.
lord and tenant, and between the tenant for life and the remainder when worth. As between the landlord and tenant it is now settled that the latter may at any time during the currency of the lease take away all such chimney-pieces, wainscot, &c., vessels and other things necessary for trade, as he has himself erected, provided he do not thereby leave the house or building in a worse condition than when he entered: but he cannot do so after the expiration of the term without being guilty of trespass. The same doctrine appears to be established as between the tenant for life and the remainder-man; but as between the tenant for life and the remainder, it is wholly the only course of husbandry, but the evidence of the estate. (1 Inst., 53 b.) The latter reason can apply only to an unenclosed country.

5. In destruction of heir-looms. The destruction of heir-looms, whether under the name of heir-looms, are considered as part of the inheritance, is waste. Thus the tenant for life of a park, Warren, fish-pond, or dove-house, who kills so many of the deer, game, fish, or doves, as not to prevent the repair or storage, is guilty of waste. (1 Inst., 53 b.)

[Tenant for Life, TENANT FOR LIFE; TESTATE, TESTATE, &c.

Permissive waste consists chiefly in allowing the buildings upon an estate to go to decay. If a house was ruinous at the time when the tenant came into possession, he is not permitted to pull it down; but if it falls down, he is not bound to repair it; but it is waste to pull it down, unless he rebuilds it. (1 Inst., 53 a.) It is a general rule that the waste which arises from the act of God is excusable, as if a house falls in consequence of a tempest. But if the destruction of the house by an unseemly heap has been owing to its being out of repair, the tenant is guilty of waste; and so he will be if he do not repair a house which has been uncovered or damaged only by tempest. In the same manner, if the banks of a river, while in a state of nature, are also destroyed, in order to the preservation of the tenant is not answerable. (1 Inst., 53 a.) But in these and all similar cases, it will still be bound to repair or rebuild, if he have entered into a general covenant to repair. (Tenant and Landlord.)

Tenants in tail, as they have estates of inheritance, are entitled to commit every kind of waste; but this power continues and can be exercised only during the life of the tenant in tail. Thus if trees growing on the land, and sold by the tenant in tail, are not cut during the life of the vendor, they will descend as part of the inheritance. So tenants in tail after possibility of issue extinct, are not imprisoned for waste, but tenants for life when the estates are given without imprisonment of waste, may be restrained from wilfully destroying the estate. (2 Cha. Ga., 32.) A mortgagee in fee in possession has a right at law to bring an action of waste, being then considered as the absolute owner of the inheritance, but the waste may be restrained by a court of equity, which will direct an account of timber cut down, and order it to be applied in reduction of the mortgage debt. (2 Vern., 392.) Tenants in tail for life, tenants in remainder for life, like any other tenants for life, prohibited from committing any kind of waste. Copyholders also cannot, unless there be a special custom to warrant it, commit any kind of waste, and every species of waste not warranted by the custom of the manor or by statute as a form of waste. (5 of Ray. Ch.)

Bishops, rectors, parsons, vicars, and other ecclesiastical persons, being considered in most respects as tenants for life of the lands which they hold in right of the church, are disabled from committing any kind of waste.

The original remedy for waste was that under the statute of Marlbridge, 52 Hen. III., c. 24, which gave to the owner of the inheritance an action of waste against the tenant for life, in which he was entitled to recover full damages for the waste committed. But as this remedy was often found inadequate, it was enacted by the statute of Gloucester, 5 Edw. I., c. 5, that the place wasted should be recovered, together with treble damages for the injury done to the inheritance. No person was entitled to an action of waste against a tenant for life under these statutes, except him who had the estate of inheritance immediately expectant on the determination of the estate for life; so that if there were an unsatisfied debt, or trust of rents, then the tenant for life, and that of inheritance, the right of action was suspended. (1 Inst., 53 b.) The action of waste had long been given way to the more expeditious and easy remedy by an action of trespass on the case in the nature of waste, which may be brought by the person inremainder for life or for years, as well as in fee, and in which the plaintiff is entitled to costs, which he could not have in an action of waste (2 Sound., 252, 7); and the writ of waste as a common law action in the administration of the estate.

The remedy for waste on the death of the tenant, if the estate of the tenant was benefited by the injury inflicted, as if money was derived to it from the sale of timber cut down, it being considered as a detriment to that course of husbandry, which might have been sustained against the executor. (Cope, 37.) Now however, by the 3 and 4 Wm. IV., c. 42, s. 2, remedies by action of trespass or trespass on the case are given against the executors of any deceased person for any cause committed in his name or for the benefit of his estate, or personal property of another within six months of his death, provided the action be brought within six months after the personal representatives have taken upon themselves the administration of the estate. But in the cases of waste that arise after the death of the tenant, if cases of waste is that in the Court of Chancery, which, upon application to it by bill, will not only direct an account to be taken and satisfaction to be made for the damage done, but will interfere by mandamus to restrain the continuance of the waste or future waste. The Court of Equity will grant its assistance against the commission of waste wherever the case appears to require it, and though the plaintiff is not in a condition to maintain an action at law. (3 Atk., 91, 211.) Thus when the tenant trusted to the tenants in remainder, the Court of Chancery will not allow waste to be committed by collusion between the tenant for life and the owner of the next vested estate of inheritance, to the prejudice of persons not in esse; and where the tenant for life in remainder is an infant, then the Court will intervene for the preservation of the inheritance, subject to contingent remainder in tail, the court has interfered to prevent him from committing waste to the prejudice of intermediate contingent remainder-men. (Cruise, Dig., tit. 2, c. 7.) On the other hand, where the tenant in possession has ceased to have an interest in the court, or if it appears that it would be beneficial to the persons entitled to the inheritance to cut down timber on the land, the court sometimes directs it to be done. (Timber and Timber-Trees.) It will also grant an injunction against waste pendant life; and in such cases it is not necessary that the plaintiff should wait till waste is actually committed; it is sufficient if an intention to commit waste appears, or if the defendant insists upon his right to do so. (2 Atk., 648.)

It has long been usual when estates for life are expressly limited, to insert a clause declaring that the tenant shall hold the lands without imprisonment of waste. These words were originally intended merely to exempt the tenant from the imprisonment of waste for cutting down timber; but it has long been settled that they enable him to cut down timber and to convert it to his own use. The powers of the tenant for life under this clause are, however, so far restrained in equity, that he is not allowed to commit malicious waste, but he may cut down trees for necessary timber serving for shelter or ornament to a mansion-house, nor timber unfit to be felled. (2 Vern. 738; 3 Atk. 215.) This is what is called the doctrine of Equitable Waste. But in those cases the court will not give satisfaction to the remainder-man for timber already cut down. (2 Atk., 745.) The privilege of the tenant for life under the words without imprisonment of waste are annexed in privity to his estate, and determine with it. Thus it seems that if a lease was made to one for the life of another without im-
of waste, with remainder to him for his own life, he would become punishable for waste, the first estate being merged in the second. (11 Rep., 83, b.) Some cases which have arisen where partial powers to commit waste had been given, are treated by the court upon the same principles as those in which the estates were given generally without impeachment of waste.

It has been stated that ecclesiastical persons, being considered in the light of tenants for life, are disabled from committing waste, though, like them, they have the right to take from the land materials for necessary repairs. They may not only fell timber and dig stones for that purpose, but have even been allowed to sell timber or stone, when the money was to be applied in repairs; also, though they cannot open mines, they may work those already opened. (Amb., 176.) By the statute 35 Edw. I. it is declared that persons shall not presume to fell trees growing in the churchyard, but when the chancel or body of the church requires reparations; and it is said by Coke that dilapidations of ecclesiastical places, houses, and buildings are a great cause of deprivation (3 Inst., 204.) Ecclesiastical persons may be proceeded against for waste in the civil as well as ecclesiastical courts. It has been held that an action on the case will lie against them for dilapidations, and may be brought by the successor to a benefice either against his predecessor or his personal representatives. (3 Lev. 206; 2 T. R. 630.) It seems doubtful whether the courts of common law have any power to issue a prohibition against the commission of waste by ecclesiastical persons. (1 Bos. and Pull. 105.) But there is no doubt as to the jurisdiction of the Court of Chancery to grant an injunction against any ecclesiastical person whatsoever to stay waste in cutting down timber, pulling down houses, or opening quarries or mines on the glebe. The proper person to make the application is the patron of the living, or, when the living is in the crown, or the application is made against a bishop or a dean and chapter, the attorney-general on behalf of the crown. (3 Mer. 421.) The patron of the living in such cases has no right to press his interest, for he cannot have any profit by the living. (Amb., 176.) An injunction has been granted against waste by the widow of a rector during the vacancy of the living. (2 Bro. c. 5, 62.) By the 56 Geo. III., c. 52, the incumbents of benefices are enabled to cut down timber, the glebe-lands for the purposes of the statute (55 Geo. III.) enabling them to exchange their parsonage-houses or glebe-lands.

(See Bacon's 'Abridgement,'art. Waste.)

WASTE LAND. [Barren Land.]

WAT TYLER. [Richard II.]

WAT. [Horology.]

WATCH. REPEATING, or REPEATER, a term applied to those watches which, in addition to showing the time on the dial, are supplied with mechanism by putting which in action the wearer is enabled at any time to ascertain the time within certain limits. In the article Horology, under the description of an eight-day spring-clock, we have shown how the number of blows given by the hammer to the bell are made to correspond with the hour denoted by the hand of the clock, and we have also shown that by pulling a string the clock would at any time repeat the hour last struck; but this would not be the case where a minute-hand had approached within about two minutes of 60, or 12 o'clock, for from that time till the hand comes to 60 the clock is on the warning, and, as will be seen by referring to the plate, is in such a position that it cannot strike at all. This defect is remedied in clocks and watches on the principle of the repeater. It now remains to show the mechanism of a repeating-watch, which, in the common acceptance of the term, means a watch which is capable of striking either on a bell or other substance the hours and quarters; but there are other repeaters which strike the minutes, and these by way of distinction are called minute-repeaters. It must here be borne in mind that those wheels and pinions which are placed between the frame-plates of a watch constitute what is called the going-train. That collection of wheels and pinions which is placed outside the frame-plates, and generally under the dial in a common watch, serves the purpose of communicating the motion from the centre wheel to the hands or pointers, and is called the motion-work. These wheels and pinions contain such numbers as will cause each hand or index to revolve in its proper place. A repeating motion in addition to the foregoing compre-

hends all those parts necessary to transmit the motion from the last-named train of wheels to the hammer, which are to strike the hours and quarters. In a repeater there is an additional train of wheels between the frame-plates, called the running or globe-wheel-work; sometimes it is called the repeating train. This train of wheels serves the purpose of regulating the rapidity with which the successive blows shall be given to the bell or other substance on which the watch strikes, and consists generally of five wheels and five pinions a, b, c, d, e, f (Fig. 1); the last pinion in the train, performing the office of a fly-wheel, is generally called the fly-pinion, and when the striking is regulated to its ordinary rate makes about 200 revolutions to each blow of the hammer.

In the following description Fig. 1 represents the repeating-train between the frame; and Fig. 2, the under side of the same frame-plate, on which the motion-work is planted.

Fig. 2.

The arbor of the first wheel, a, Fig. 1, of the repeating-train, has in it a hook which takes hold of the inner end of the repeating main-spring, the outer end of which is secured to the side of a barrel, which is fixed immovably to the upper frame-plate, which is removed to afford a view of the wheel-work; the arbor is also attached moveably to another wheel called the ratchet, R, under which is
attached to it a smaller ratchet, into the teeth of which a click is forced by a spring. The click and spring being fixed to the wheel a, so that when the arbor is turned (by the repeating-motion-work) in the direction to wind up the spring, the ratchet R turns without the wheel a, but in its effort to get back to its original position it brings the wheel a with it, and consequently gives motion to the whole of the repeating-train and also to the motion-work. In the return the teeth of the ratchet R catch m, a small moveable raising piece forming the tail of the hammer H, and cause it to strike. A spring attached to the upper frame-plate acts on the pins of the tail m, and forces the tail a little way out of the hold of the tooth of the ratchet, and to this motion in the opposite position to be acted upon by the ratchet-teeth, and at the same time allows of a sufficient motion in the contrary direction, to allow the ratchet-teeth to pass the tail during the backward motion, or which the key is being turned.

No. 2 represents the repeating-motion-work which is outside the frames, and under the dial, the dial being removed to show the work. P is the pendant-shank or push-piece, passing through the socket or pipe O. On the end of P is a pin a, fixed flat on the under side, which flat part slides against a piece of steel screwed to the inside of the case, and serves to keep the pendant from turning round, and the end of the piece of p or pins is formed with a small projecting rim or bead, which prevents the key from turning out of the key hole. Then, when the motion of the pusher, when forced in, acts on the rounded end or heel A of the lever C, whose centre of motion is the screw C, and attached to its other extremity is one end of a chain s*, which passes round a pulley B, on a stud fixed in the motion-work, and comes out of the case through one of the numbers of another pulley, A, which is fixed on the squared end of the arbor of the ratchet R, No. 1, to which the first wheel a of the repeating-train is attached as before described, and which is the ratchet of the push-piece. A and with it the ratchet R are made to revolve, and wind up the spring which is to put the repeating-train in motion; and the arm b of the lever C limits the distance to which C can be pushed, by coming in contact with the teeth of the hammer, and causes the number of ratchet-teeth in R, Fig. 1, which are to pass the hammer-tail or raising-piece m, in order that on their return, by the reaction of the spring, they may cause the hammer to strike the required number of blows.

As, 1, 2, 3, represent the steps in the quarter-repetition, Fig. 2, which is attached immovably to the cannon-pinion D, which latter carries the minute-hand and is fixed spring-tight on to the prolonged arbor of the centre-wheel (which is used for an hour).

Attached to the quarter-repetition N is the surprise which has a motion concentric with the cannon-pinion and extremity of the quarter-repetition: into the surprise Z is put a pin o, one end of which serves to limit the motion of the surprise Z by passing through a slit in the snail N, and the other end serves to shift the hour-hand L, by acting on the teeth of the star-wheel; and as soon as the pin o has shifted the star so far as to bring one of the points just past the angular point of the jumper s, the star-wheel and surprise Z are thrown suddenly forward by the jumper, and made to assume the position shown in the drawing, by the succeeding tooth to the one which has been acted upon by the pin o coming in contact with the back of the pin o. The surprise Z is moved only so far as to occur exactly as the minute-hand comes to the hour, and the use of the surprise is to receive the end of the arm b, which would otherwise be likely to come on the edge of the snail, and make the hammer fall on step without the push-piece was thrust in. When the minute-hand was at the hour, or 00, on the dial; by this contrivance the change from hour to hour is made instantaneously.

Q is the quarter-rack, whose centre of motion is Q, having the same form and proportions as F and G, and its purpose is striking double blows for the quarters, for which purpose there is another hammer N, seen in No. 1, called the quarter-hammer. K is a piece fitted on over the pulley A to the square end of the arbor of the first wheel a, Fig. 1, of the repeating-train, and serves to bring back the quarter-rack, Fig. 2, to its original place by acting on the pin G by that part of it which is formed by a straight line through the centre of A, and which does not take hold of the pin G until all the blows of the hammer denoted by the hour-hand and determined by the hour-snail have been given.

It will easily be seen how by the action of this pin K on the pin G, which is the same length and made to act in rapid succession on the two pieces q and g, which are attached to the prolonged axes of the hour and quarter-hammers, and are acted on by springs 9 and 10, so as to allow the teeth of the quarter-rack to pass the quarter-repetition, which latter determines the number of quarters to be struck, according as the rack falls on the steps 1, 2, and 3, into which positions the rack is thrown by a spring D. When the arm a by acting on G brings back the quarter-rack to the position of the second movement, with the nothing piece TR, giving it, together with the star-wheel, a small degree of motion concentric to T, the quantity of motion being limited by a stud fixed in the frame-plate, and passing through a small opening or hole in TR at z, in which the arm is kept in its position by a spring i, fixed on TR acting against the stud in the plate. The hour-hammer has in it a pin, 3, coming up through an opening, 3, in the plate; the spring r acts on this pin, and causes the hammer to strike; it has also another pin, 2, coming through the case, and retaining the pin 3, as already mentioned, in the quarters; the quarter-hammer has a similar pin coming through opening 4, on which spring 7 presses for a similar purpose.

When the quarter-rack is brought back to its original position, namely, that which it had before the motion of the key, it is carried to the opposite end of the quarter-repetition, which was brought beyond the end of R of the all-or-nothing, which in its passage m will have pressed outwards: when m has passed the end R, TR is brought back to its place by i, z, and prevents the motion of the quarter-repetition, and the quarter-rack, which, when the rack is brought home, acts upon the raising piece or tail m (No. 1), through the medium of the pin I, which is fixed in it, and turns it into such a position that it shall not engage with the teeth in the ratchet R, which serves the important purpose of preventing any blow from being struck unless the push-piece is pushed quite home, so that the arm b comes in contact with the hour-hand L, and gives motion to the all-or-nothing T R, which, by releasing the quarter-rack, sets it in motion by the spring i, and allows the raising-piece in No. 1 to take the proper position for engaging with the teeth in the ratchet R (No. 1): 12 is a stud to carry the minute-wheel, which, as well as the hour-wheel, is omitted to prevent confusion. It may be remarked that, when the key is turned, the presence of the quarter-snail which is marked h is in such a position as to receive the end of the quarter-rack upon it, the hour only can be struck, as it does not admit of sufficient motion to bring the hammer N into position, nor does it allow of the minute-hand, when the surprise flies forward, and, should the watch be struck immediately, would receive the end of the quarter-rack, and prevent any more than the hour being struck.

WATCH AND WARD is the ancient provision for the maintenance of the public peace and of property in towns: watch is related to the night, word to the day. The duty of keeping watch and ward no doubt prevailed in Anglo-Saxon times, although it is usually stated to have been imposed by the statute of 1160 (c. 4). The words of the statute are — And henceforth it is commanded that watches be made as formerly they were accustomed to be; that is to say, from Ascension-day to Whit-day in every parish, by the churchwardens of every church, or by four men, according to the number of inhabitants; and that they watch all the night from sunset to sunrise. And if any stranger pass by them, he shall be arrested.
The duty of keeping watch is imposed upon every inhabitant of the group, which is essentially a small community. The watchman must be suitably armed, and women or infirm persons must find substitutes. Not to keep watch in his turn, or not to find a sufficient substitute, is an offence for which the party may be indicted at the sessions of the petty court. It is also punishable by fine and imprisonment.

Another class of watchmen, having like powers and duties to the former, is that appointed by the justices for the preservation of the peace. [Constables.]

WATCHE. [Somersetshire.]

WATCHEO. [SOMERSETSHIRE.] WATCHEO is said to be the largest island of a small group situated in the Pacific between the two larger groups of the Society Islands on the east and the Friendly Islands on the west. It is a small island, with a circumference of about 18 miles. The surface is composed of hills and plains, and the soil is light and sandy along the beach, but better farther inland. The shores are lined with reefs or rocks, which extend to distances that are not easily obtained in some parts. As the island is very low, and has steep walls, so that it cannot be approached by vessels. It has abundance of cocoa-palms, bread-fruit, plantains, and sweet potatoes; and of animals, especially hogs. A great part of it is covered with trees. The number of inhabitants is perhaps about 4000, and that of the women is estimated at 16,000. They resemble in size, colour, and form the inhabitants of the Society Islands, and their language does not differ much from that of the neighbouring groups. The island was discovered in 1757 by the French navigator, Captain James Cook. He spent some time there, and when he left, the island was in the hands of the missionaries, about twelve years ago, went there from the Society Islands. It is stated that since then they have advanced considerably in civilization. (Cook's Third Voyage: Missionary Report.)

WATER. [W. And J. ROBINS, ENRRI, receveur-general des finances, was born at Paris in 1718. Watelet was distinguished as one of the best French critical writers upon art and was also an excellent amateur painter and copper-plate etcher. He was the son of Henri Watelet, receveur-général des finances de l'Orleáns, and was educated at the college of Harcourt. He visited Germany and Italy in his youth, and spent some time at Rome, where he formed a friendship with the French painter Pierre, and became one of the pupils of the French school at Rome. He then returned to France, and entered the army. When the society in Paris, he retired to the country-side of Moulinjoli, belonging to Madame Le Comte. Here he wrote his didactic poem, 'L'Art de Peindre,' which was published in 1761. In the same year he was elected a member of the French Academy, and near the same time, the first part of a work entitled 'De l'Origine et de la Destination des Arts Libéraux,' the second part was never published. After this time he paid a second visit to Italy, in company with his friend M. de Silvole, and Abbé Beclere, having previously visited Holland and Belgium. He was everywhere well received on his journey, and was much noticed by the king of Sardinia and the pope Rezzonico, Clement XIII. He was made member of the academy of the Sciences of the arts; and in 1774, he was elected a member of the Institute of Belles Lettres. After his return to France a second time, he published, in 1774, his 'Essai sur les Jardins,' and in 1784 was published a 'Recueil de quelques Ouvrages de M. Watelet.' This collection contains several dramas, some of which have been acted. He died in 1760, leaving a son who spent a long quiet sleep. His eloge was read a few days after his death, at a public solennity of the French Academy of Medicine, by M. Vicq D'Azay, the secretary of the Society, of which Watelet was an associé libre. He was also an honorary member of the French royal academy of painting and architecture, and a member of the academy of Berlin.

The chief work of Watelet's life was his 'Dictionary of the Arts of Painting, Sculpture, and Engraving,' which was not published until after his death—Dictionnaire des Beaux-Arts, translated from the French by W. and J. Robins, published in Paris, 1792. Watelet left the work incomplete, and it was finished by M. Levesque, of the French Academy of Inscriptions and Belles-Lettres. Watelet etched many plates: Huber, in his 'Manuel des Artistes,' &c., etched more than 27 portraits in 48 plates. A cubit inch of water at 62° Fahr., and 30 inches barometric pressure, weighs 222-456 grains, and as a cubic inch of atmospheric air weighs 0-91 grains, it is rather more than 815 times heavier than an equal volume of air.

Water, like all other fluids and substances, expands by exposure to an increase of temperature, and, with a curious exception, the dilatation within certain limits is proportionate to the degree of heat to which it is subjected. It is a very important property; for if water were less than a point more dense than exactly at its freezing point, it would be less dense than exactly at its boiling point: for example, if water at 40°, which is the point of its greatest density, be cooled, it expands as it cools till reduced to 32°, when it solidifies, and this constitutes the exception to the law of its expansion by reduction of temperature: if, on the other hand, it be heated, it expands as the temperature rises, and this is conformable to the general law. This expansion of water by cold produces very important effects in the economy of nature; for if it increased in density, the frozen portions would sink down successively, and thus large bodies of water would become masses of solid ice.

When water is heated to a certain point, which is arbitrarily fixed on the scale of Fahrenheit's thermometer at 212°, it acquires the greatest temperature which it can possibly possess, it then boils, and is converted into vapour. A little before ebullition commences a slight noise is heard, which is commonly called simmering; this arises from the formation of small bubbles of vapour or steam at the bottom of the vessel, which, as they ascend, break into the upper and colder portion of the water; in this they are condensed, and the noise results from the sudden condensation of the bubbles of vapour.

Steam at 212° occupies about 1700 times as much space as the water does at 32°, which is the temperature at which it is generated. It is upon the elastic force of steam communicated by heat, and the instantaneous annihilation of it by cold, that the working of the steam-engine depends. Though we can calculate with the average atmospheric pressure, and acquire no higher degree of temperature than 212°, when heated under pressure it acquires a much higher degree of heat; and it is a curious fact that the steam issuing from what we
tended a high-pressure boiler does not scald when water is received on the hand; which is probable, not that it is capable of two causes; first, the conversion of the steam with cold air; and secondly, to be kept perfectly still, it may be reduced below this temperature and yet retain its fluidity, but by agitation solidification ensues, and the temperature rises to 32°. The force with which water assumes the solid state is so great, that iron vessels of great thickness have been found, and glass vessels of lead, pipes are laid, known to be destroyed in winter time from the same cause. Ice is lighter than water, its density being 0:94, and hence it floats on water. The subject of the discovery of the composition of water has lately excited considerable discussion; for we are generally convinced that the claim of Mr. Cavendish as the author of this great discovery, and which has been for some years assigned to him without dispute, is rightly so attri-

WATER. Several of the uses of water having been already stated, either under the article Bathing or that of Foon, it is intended to treat here of what may be termed the natural history of water, both simple and mineral, embracing also an account of the several classes of water, especially of such as suffer from contamination.

Water is commonly divided into certain heads, according to the source whence it is obtained, viz. into atmospheric water, including rain and dew; and into terrestrial water, comprising spring, river, well, lake, marsh, and sea. Looking at it from the last point of view, water, being the order now given will afford convenient opportunities of stating the peculiarities of each, after some general statements of the properties common to all. Pure water is a colourless, transparent, tasteless, and odourless compound, at the ordinary temperature of 32° F. (except near the poles and the summits of lofty mountains), having neither an acid nor alkaline reaction, and being assumed as the standard, of the specific gravity 1.000. It is seldom found in a state of perfect purity, but, from its great solvents and absorbent power, it is in-pregnated with a variety of saline substances, gases, and animal and vegetable substances, either living or undergoing a process of decomposition. The effect of these is to communicate different properties, and generally give it a peculiar taste, and not unfrequently an odour, which, if not cognizable by the blunted senses of man, is so by animals, especially the camel, which can scent water at a great distance in the desert. The specific gravity of land water is often modified by the saline nature of the soil, especially that of certain springs and of the great rivers, from the quantity of mud and other matters which they contain.

Rain-water is commonly reckoned the purest; but it is by no means free from accidental impregnations as is generally supposed. Whatever foreign ingredients exist in the atmosphere of any place are brought to the ground by the first rain that falls;—thus, it often contains traces of munitions, of free muriatic acid, nitric acid, carbonic acid, and of carburetted hydrogen gases; minute quantities of iron, nickel, and manganese; as well as of a peculiar organic substance, chemically different from the extractive matter and the gluten of plants and animals, called pyrrhyte. (Dubeny, Report, p. 1.) Occasionally phosporylic acid is found in it, especially when the wind blows from the north-west. Much more important is the presence of ammonia, insisted on by Liebig (Chemistry in its Application to Agriculture, p. 75, 2nd edit.) as the chief source of the nitrogen of plants. Rain-water has high solvent powers, which fit it well for the part it has to perform in the economy of nature, and also for many operations in the laboratory. In this respect it is nearly equal to distilled water. When collected in the natural reservoirs of towns it is often kept strained; and is always contaminated with some soluble and generally dangerous salt of lead, when collected from leaden-roofs or transmitted through leaden pipes or cisterns.

LADD. This differs little from rain, save in containing more atmospheric air. [Dew.] Ice-water differs, when first obtained, from rain, in being destitute of atmospheric air, and hence it cannot sustain respiration in fishes; it is for the same reason marshy and insipid; but by exposure to the air it speedily absorbs a due proportion. Snow-water is near similarly. It is said, that, or being exposed to the air, in being destitute of atmospheric air, and hence it cannot sustain respiration in fishes; it is for the same reason marshy and insipid; but by exposure to the air it speedily absorbs a due proportion. Snow-water is near similarly. It is said, that, or being exposed to the air, it speedily absorbs a due proportion.
apt to become so if kept in a reservoir lined with bricks, unless they be coated with an insoluble cement. The water from old wells is more pure than from recent ones, the soluble particles having all gradually washed away. The pump and well water, if pure or putrid, may be rendered pure by adding alum or recently prepared charcoal, or by simply pouring it from one vessel to another in the sun.

Water of the ocean abounds in saline matters so much, that it is unfit for use, except in small quantity as a medicine. The quantity of salt in this water is uniform, while the water of the Southern ocean contains more salt than the Northern, while the proportion present in the water at the equator holds the middle place between the two. This sea water may be made fit for drinking by pressure, filtration, and freezing, or simply by boiling it, and condensing the steam as it arises.

Distilled Water.—For many chemical, pharmaceutical, and even dietetical purposes, water must be of greater purity than it is generally found. For this end, it is usually to be distilled, in which process never more than two-thirds of the water put into the still should be allowed to pass over.

Boiled Water.—This is water boiled and poured on toasted bread, which in some degree lessens the rapid taste. An agreeable and beneficial degree of salinity may be communicated to water which has been long boiled, by adding, previous to drinking it, a little of the common soda-water, which is merely carbonic acid gas diffused through the water under some pressure.

Mineral Waters.—Dr. Gairdner, in his Natural History of Mineral and Thermal Springs, has endeavoured to generalize the connection between the composition of mineral waters and the rock formations from which they flow:

1. The salts held in solution in mineral waters have often no connection with the acid, saline, or earthy matters which enter into the composition of the rocks which are supposed to be the source of the waters, but which seems to be the first index that such waters cannot derive their origin from these formations.

2. The mineral waters of the primitive formations are almost all thermal, and generally possess a very high temperature. Their predominant impregnation is usually sulphurated hydrogen gas, free carbonic acid gas, carbonate of soda, and in general salts with a base of soda, silica, few calcarious salts, except the carbonate of lime in some peculiar situations, and but a small quantity of iron.

3. The waters of the transition and older secondary formations participate in those belonging to the primitive rocks. They are generally of a lower temperature, though they may be very hot; free carbonic acid is much less common, and sulphurated hydrogen is almost entirely absent. Salts of soda still predominate, but the carbonate is not so common, and the sulphate of lime is found in the greater number of these waters. Silica exists in two or three examples.

4. The waters of the newer secondary and tertiary formations are as distinctly characterized as those of the primitive rocks, placed at the other extremity of the series. They are all cold. Free carbonic acid is almost entirely absent. Their predominant ingredients are the carbonate and sulphate of lime, sulphate of magnesia, and oxide of iron.

5. The trachytic and basaltic formations, and modern volcanic rocks, present in their mineral waters marks only in a few spots and in the cases in which they are found in the waters of the granite and other primitive rocks. Sulphurated hydrogen, carbonic acid, carbonate of soda, carbonate of lime, and silice repassar, and many other substances and minerals which the temper of the water is aquatic.

6. It is often found that the mineral waters of a district have almost the same composition, in which case they generally issue from the crystalline and independent formations. In other cases they are subject to great variations, and depend on a comparison of a totally different composition rise close to each other, when they emerge from sedimentary rocks.
Mineral waters, though generally characterized by possessing some principle different from what is found in common water, or some of the ordinary principles in usual proportion, yet among these are reckoned certain springs which have no claim to distinction beyond their character to their extreme purity, such as Malvern and Holywell; or to having a higher temperature throughout the year, than the mean of the latitude where they are situated. There are others, among other springs, which are properly divided into two sections, the mineralized hot springs and the unmineralized, among which are some only tepid, such as Matlock, where some springs are 69°, the lowest of the class in Britain, and others cold, presenting an elevation of the temperature, to thirty yards above the level of the river Derwent, whilst those which arise either above or below this range cold. For practical purposes mineral-waters may be classed under four heads, each susceptible of secondary heads, according as they are hot or cold, or have other peculiarities, viz.: saline, alkaline, chalybeate, and sulphureous. It will not be possible to mention more than a few of the most important of each.

Hot or aperture springs: of these some are hot, others cold. The chief are Carlsbad, Marienbad, Egra, Kissingen, Wiesbaden, Baden-Baden, Seidlitz, and Saidschuft, with Pullna, in Germany; Cheltenham, Leamington, and Harrogate in England; Dunblane, Pitcaithly, and others in Scotland.

Alkaline waters, owing their properties to different saline principles, are found at Carlsbad, Marienbad, Kissingen, Pullna, Saidschuft, Ema, Töplitz, and Wiesbaden, in Germany; Vichy and Mont d'Or, in France; Harrogate, Scarborough, and other Yorkshire springs, Cheltenham, Leamington, Bath, and elsewhere, in England.

Chalybeate waters: with these acridulous waters are often reckoned, as the iron is often associated with much free carbonic acid gas. Some of the chief are Spa, Pyrmont, Jermyn's Wells, Marienbad, Ask-la-Chapelle, and Selzter in Germany; Tonbridge, Harrogate, and Brighton, in England, and Peterhead, in Scotland.

Sulphureous waters: Aix-la-Chapelle, in Rhine Prussia, Burgsee, clean springs, are hot; Harrogate, Ask-la-Chapelle, and others in Yorkshire, cold; Moffat and Strathpeffer, in Scotland, also cold.

Joduretted and other waters. Many springs have of late been found to contain a notable quantity of iodine or bromine, others contain both; Creuzach, in Germany, contains both, but most iodine; Llandrindod and Builid in Radnorshire, the springs issuing from the lias at Leamington, Gloucester, Tewkesbury, and Cheltenham, contain iodine; bromine, but not iodine, exists in small quantity, in the same water near London, in the springs from the coal-formation of Asby-de-la-Zouch, Newcastle-on-Tyne, and Kingswood, and Bannning near Edinburgh: Woodhall, near Asby-de-la-Zouch, contains most iodine of any British springs yet investigated.

Organic matters, termed Boregine, glairine, zoogene, &c., have been found in many springs. Of these an account may be found in Dr. Lankester's Aeshern and its mineral springs, p. 103.

WATER LAND AND TITLES. The right of conducting water through a estate for the use of the other is an incorporeal hereditament of the class of easements, and was known in the Roman law by the name of the servitium aquae ductus. The right of taking water out of the well or pond belonging to another person is an incorporeal hereditament of the class of profits called in the civil law the servitium aquae haustus. (Domat, Civil Law, 1. 1, t. 12.) These rights, in our law, must be either derived from a grant or established by prescription. [Prescrip-] It is the settled law of England that water flowing in a stream is originally publici juris, that is to say, a thing the property of which belongs to no individual, but the use to all. Prima factae the proprietor of each bank of a stream is the proprietor of one half of the land covered by the stream, but there is no propriety in the water. Every proprietor has an equal right to use the water which flows in the stream, and consequently no one can have the right to use the water to the prejudice of any other without his consent. No proprietor can either diminish the quantity of water flowing over his land, or altogether prevent the water passing from his estate, nor throw back the water upon the proprietors above, so as to overflow or injure their lands. For the same reason no proprietor has a right so to use the water of a stream as to injure its quality to the detriment of other proprietors.

The only modes in which a right to the use of running water in a manner inconsistent with the common law rights of others can be established, are either proof of an actual grant or licence from the persons whose rights are interfered with, or proof of an uninterrupted enjoyment of such a privilege for such a period as the law considers sufficient to constitute a right by prescription. The period of twenty years had been generally fixed upon by the courts of law and equity for this purpose, and the Act 3 Will. IV. c. 71, which substituted a period of thirty years, was adopted in the late Prescription Act (2 & 3 Wm. IV., c. 71, s. 2), which converts what was formerly only a prescriptive into an actual right. [Prescription.] But where water had been left unappropriated, it seems that the person first taking the water, after appropriating it, and rendering to the owner for a violation of such right an action may be maintained on an enjoyment of less than twenty years. Thus it has been decided that after the erection of works and the appropriation by the owner of the land of a certain quantity of the running water, if the water runs over, and takes what remains of the water before unappropriated, the first-mentioned owner, however he might before such second appropriation have taken to himself so much more, cannot do so afterwards. (6 East, 219.) The privilege of taking water from the second owner, after the period of twenty years, was held to be a nuisance, and may be continued in a corporation or, may be prescribed for by the inhabitants of a township or parish. If land with a run of water upon it be sold, the water privas factae passes with the land; but if the land be taken in fee simple by an owner as aquam eam, the soil will not pass, but only a right of fishing in that water; for the proper words in that case to pass the soil would be, so many acres of land aquae cooperias; whereas the word stagnum, or pool, will pass both water and land. (1 Inst. 43.) The exclusive right to a flow of water once acquired can only pass by grant as an incorporeal hereditament, and a licence, by parol or otherwise, to use or take the water at any place, may be revoked even without an express power of revocation by the grantor or licensor, unless works have been constructed and expenses incurred upon the faith of it. (5 B. & Ad., 1.)

When the owners of property have by long enjoyment acquired special rights to the use of water in its natural state as it was accustomed to flow, by way of pasturage or easement to their own properties, and not merely as a use, which is common to all the king's subjects, an action may be maintained for a disturbance of the enjoyment; but where the injury, if any, is to all the king's subjects, the only remedy is by indictment. The mere obstruction of the flow of water which has been accustomed to flow through a person's lands does not in itself afford a ground of action. The plaintiff in such an action must be enabled to show that the water is the same water which was going through his lands, of which he has been deprived, or at least that some deterioration was occasioned to the premises by the subtraction of the water; but where the proprietor of the lands can prove that he was not required to pay the diversion the defendant is entitled to his action to show that the defendant was the first person who appropriated the water to his own use, unless he has had twenty years' undisturbed enjoyment of it in its altered course. Where the injury occasioned by the diversion or obstruction of water is of a permanent nature, and has caused the reversion, an action may be brought by the reversioner, as well as by the tenant in possession, each for his respective loss.

The diversion of watercourses or injury to their banks so as to cause inundation is nuisances against which a court of equity will protect parties by injunction; and if there be a question as to the right to the flow of water, an issue
will be directed to try it. Although a court of equity will not in terms decree the banks of rivers, watercourses, or navigable canals to be repaired, the effect of such an order may be obtained by an order that parties shall not be at liberty to use the said bank, or the said watercourse, or against their using the same by the obstructions consequent upon a state of disrepair. An injunction may also be obtained against conducting water from one man's tenement to that of another, to the injury of the latter, by directions to watercourses, being put in abeyance for the purpose of preventing the wet plaster, require simply water (distilled or boiled) as a vehicle; the lime itself, as it dries, binds them. The mixture of lime and sand for the intonaco, or fine and last coat for painting upon, must be prepared and kept moist some months before it is used, or otherwise it degrades the water-colours. The following interesting details relating to the practice of fresco-painting, both of the old Italian and the modern German masters, the reader is referred to the Appendix to the Report of the Commission on the Fine Arts, presented to both Houses of Parliament by command of Her Majesty, in 1842. All pigments, as those prepared from animal and vegetable substances, cannot be used in fresco-painting on account of the lime in the ground, which destroys them; yet some can be used, and are prepared for this purpose; or, a substitute is made for them, and a suitable colour for every purpose. The following are the colours used by Professor Hess, the eminent German fresco-painter: white—lime which has either been long kept or rendered less caustic by repeated manipulations and dry-well; yellow—reddish earth; and yellow ochres, burnt ochres, burnt sienna, oxides of iron and lake-coloured burnt violets: green—terra-vert, cobalt green, and chrome green: blue—ultramarine, pure and factitious, and cobalt: brown—burnt and raw umber and burnt terracotta: purple—but violet, cobalt, and raw ultramarine. The following are the most permanent colours, and therefore most valuable to the water-colour painter: blues—ultramarine, French ultramarine, cobalt, indigo, and small: greens—Indian red, light red, Venetian red, scarlet vermilion, carmine, pink, and vermilion; maroon, purple lake, and red ornament: yellows—cadmium yellow, gamboge, yellow ochre, Indian yellow, mars yellow, lemon yellow, Roman ochre, brown ochre, mars orange, raw sienna, Italian yellow, gamboge, and gamboge; burnt sienna, Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greens—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: brown, pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greys—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greys—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greys—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greys—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greys—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greys—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown: greys—emerald green, olive green, and green oxide of chromium: reds—alizarin crimson, and ivory black, and yellow; violet—Indian purple, and burnt carmine: browns—burnt sienna, brown pink, burnt umber, Van Dyck brown, sepia, maroon, Cologne earth, bistre, and madder brown.
the use of their holy water from this ancient custom; but Du Fresne seems to speak more properly when he says their lustral water rather succeeded in its room. Bingham is himself inclined to deduce the modern custom 'from the same source in the church, or at least it is associated with holy water' (properly, sprinkling-vessels), so often spoken of among the heathens; and he quotes a passage from Sozomen, where that ecclesiastical historian, speaking of the emperor Julian's going into a temple in Gaul to sacrifice, with Valentinus attending him, 'saw his priest sprinkled them with water as they went in, according to the heathen custom'; upon which his editor, Henry Valesius, has observed that the reading in some copies is 'according to ecclesiastical custom,' the more modern tradition, and he quotes the passage in the sense. (See also ch. x., § 5.) Holy water is also used in the Greek church, but without salt. The mixture of the salt and water is interpreted by some Roman Catholic divines as that which is called the hyposcarum of the nature of Christ, the salt being the emblem of his divinity, the water of his humanity.

WATER-LILY, the common name of several plants remarkable for their beauty, belonging to different genera of the family Nymphaeaceae. Nymphaea and Nuphar are called Water-Lilies. The genus Nymphaea has a calyx of four sepals girding the base of the torus. The petals, 16 to 28, adnate to the torus, elevated about the ovary and covering the same, and therefore at first sight appearing to be stamens, are united. The stamens are numerous, disposed in many series, and inserted in a similar way above the petals. There are upwards of twenty species of this genus described. They have all large floating leaves, with white, red, or blue flowers, which appear at any season.

N. caerulea, Blue Water-Lily, has peltate nearly entire leaves without dots, glabrous on both surfaces, and 2-lobed at the base, the lobes free; the anther with an appendage at the apex; the stigmas, 10-rayed. This plant is a native of the northern United States, the fresh-water ground of Ohio, Indiana, Ohio, and Tennessee. The flowers are very fragrant, and from its frequent representation in the sculptures of Egypt, it appears to have been regarded as a sacred plant by the antient Egyptians.

N. edulis, the edible Water-Lily, has peltate, broad, oval, entire leaves, with the under surface pubescent. This plant is a native of the East Indies, in wet fenny districts. Its flowers are small, and white or reddish. Like all the species, it has large pinnate roots, which contain an abundance of starch and the rhizomes are used for articles of diet. The seeds also of a species nearly allied to this, the N. rubra, which has deep-red flowers, are also used as an article of diet. Its flowers also are held in superstitious veneration by the Hindus in the districts of the East Indies in which it grows.

N. pubescens has peltate, sharply-toothed leaves, obliquely reniform, with the under surface pubescent and spotted, and the lobes roundish. It is a native of the East Indies, Malacca, the Moluccas, and Borneo. It has been found also at Weere and Aera on the western coast of Africa. This plant is called Lotos throughout India, and is held sacred by the Hindus. Its flowers are of a beautiful white. They expand during the day and close at night, the flowers of the morning being of these, and the roots of the evening. The seeds are large, and very much in use in India for making polishes.

N. Lotus, the Egyptian Lotos, has peltate leaves, sharply serrated; the under surface is pilose at the nerves, and pubescent between them. This plant is a native of Egypt, and grows in slow-running streams, especially in the Nile near Rosetta and Damietta, and has been found also at Weere and Aera on the western coast of Africa. This plant is called Lotos throughout India, and is held sacred by the Hindus. Its flowers are of a beautiful white. They expand during the day and close at night, the flowers of the morning being of these, and the roots of the evening. The seeds are large, and very much in use in India for making polishes.

Lotos. The Lotos of the Egyptians was the Zizyphus Lotos; that of Homer and Dioscorides, a species of Lotos or Trifolium. The Lotos of Hippocrates is the Cetis australis; and the Italian Lotos is the Diospyrus Lotos. L. rubra, the common or Water-Lily, has cordate, quite entire leaves; the stigmas 16-rayed, the rays ascending. This plant is a native of ditches, ponds, and lakes throughout Europe, and is abundant in Great Britain. The flowers are white, and, according to Linnaeus, open them- selves at the close of the morning and close in the morning, opening at about four o'clock in the evening. This plant is very deservedly highly esteemed as the most beautiful of European plants. It is frequently accompanied with the yellow water-lily, and the two together give an exceedingly graceful appearance and a very pleasant smell. The roots of the white water-lily contain an astringent principle, which renders them useful in dyeing. They also contain starch, and on this account swine feed on them, although other animals reject them. The whole plant was at one time regarded as medicinal, but it is now thought to be injurious. It is not only its beauty, although it has a popular reputation as a remedy in many diseases. There is a variety of this plant occasionally met with, called minor, which has smaller flowers and leaves than the species

N. odorata, Sweet-scented Water-Lily, has cordate, quite entire leaves, with the nerves and veins on the under surface very prominent; the stigmas 16 to 20 rayed; the rays erect, inflamed at the top. This plant is a native of North America, from Canada to the Carolinas. It is found in ditches and slow-running rivers. This plant is often confounded with the European Lily, but it is quite distinct. Its flowers are white tinged with red, very fragrant, and opening in the morning, close at night. The roots of this species are also white, and are of the same size. They are the root of the black dyeing plant, which has been used in the manufacture of a black dye. It is called N. pubescens, which is from the same species as the white water-lily, and the black flower is claimed to be a beautiful one.

N. regia. This splendid plant, in the dimensions of its leaves, their colour, the colour, size, and fragrance of its flowers, may be regarded as the queen of flowers. The following is the account of its discovery by Mr. Schomberg:

It was on the 1st of January, while contending with the difficulties nature opposed in different forms to our progress up the river Berbice, that we arrived at a point where the river expanded and formed a currentless basin: some object on the southern extremity of this basin attracted my attention; it was impossible to form any idea what it could
be, and animating the crew to increase the rate of their paddling, we were shortly afterwards opposite the object that had raised my curiosity—a vegetable wonder.

A call for botanists was at once made; and the young frog was, I felt, my reward. I felt as a botanist, and felt myself rewarded—a gigantic leaf, from five to six feet in diameter, salver-shaped, with a broad rim, of a light green above and a vivid crimson below, resting on the water.

Quite in character with the wonderful leaf was the luxuriant growth of many hundred petals, pastel in their alternate tints from pure white to rose and pink. The smooth water was covered with the blossoms, and as I rowed from one to the other, I always observed something new to admire. No specimens of this plant have been yet seen alive in this country, but seeds have been received from Mr. Schonburg, and it is hoped that this splendid plant may yet flourish in our gardens. The leaves are very large, measuring 5 or 6 feet in diameter. They have an orbicular form, the upper surface is bright green, and they are corrugated with a rim round the margin from 3 to 4 inches in height; on the inside the rim has a green colour, and on the outside, like the under surface of the leaf, it is of a bright crimson; they have prominent ribs, which project an inch high, radiating from a common centre; these are crossed by a membrane, giving the whole the appearance of a spider's web; the whole leaf is beset with prickles, and when young is convolute. The stalk of the flower is an inch thick and studded with prickles. The calyx is 4-leaved, each sepal is 7 inches in length and 4 inches broad. The corolla covers the calyx with hundreds of petals; when first opened it is of a white colour, but subsequently changes to pink; it is very fragrant. Like all other water-lilies, its petals and stamens pass into each other, a petal often being found surmounted with half an androecium. The seeds are numerous, and embedded in a spongy substance. This plant has by some botanists been placed in the genus Euryale, whilst Lindley thinks it is nearer Nymphaea, from which it differs in the sepals and petals being distinct, the papilla of the stigma being prolonged into a horn, and the changing colour of its petals. Of this genus there is but one species at present described.

In the cultivation of water-lilies, those brought from warm climates should be grown in large pots or pans of water, with several inches of rich loamy soil in the bottom, which should be placed in a warm part of the stove. The hardy species may be planted in ponds, cisterns, canals, or lakes, with a rich loamy soil at the bottom. They may be propagated by seeds, or dividing their roots or tubers, when placed in the water where they are intended to remain. A due supply of water should be ensured for their growth, as they will not prosper after being exposed to the atmosphere or cold.

(From 'Gardener's Dictionary'; Lindley's 'Monograph on Victoria regia'.)

WATER-MEADOWS. (IRRIGATION.)
WATER-NUT. [Trapa.]
WATER-OAK. [Quercus.]
WATER-OUSSEL. [Cinclus.]

Genera and Species. [Meek.] [Bull. Cl. vol. xv., p. 122.]

The Cinclus haunt the banks of clear streams, rejoicing in the vicinity of some tumbling cascade hurrying over a rocky declivity. They go into the water till they are quite submerged, walk on the bottom of the stream, and seek their insect food. M. Temminck states that when in this situation they open their wings and constantly agitate them. Their feathers are, he says, furnished with an oily matter for this purpose, like the feathers of ducks; and adds, as an on dit, that when thus walking they appear surrounded with air-bubbles, which render them very brilliant.

The following are European:

Cinclus aquaticus, Cinclus melonogaster, and Cinclus Pallasi. M. Temminck expresses a doubt whether the second is a distinct species; and refers, with some slight doubt, Cinclus Pallasi of the Himalaya Mountains to the third. He states the geographical distribution of Cinclus Pallasi to be the Crimea, and other parts of European Russia, and says that it is very common in Japan, where it is named Konjusadara.

We select as an example the first of these.

Description.—Male.—Upper parts deep brown, tinted with ash-colour; throat, front of the neck, and breast, pure white; belly, rusty; bill black; iris pearl-grey; feet supernumerary. Length, body, 7 inches; wing, 9; half wing, 4 3/4 in.

Female.—Upper part of the head and back part of the neck ash-brown; lower parts; white upon the breast; lower parts yellowish rusy.

Young of the Year distinguished by the grey feathers which cover the head and the nape; feathers of the back and rump fringed with blackish; those of the wings with white towards the end; the white of the lower parts extends to the middle of the belly and towards the abdomen; but all these white feathers are finely varied with brown and ash-colour.

This is the Lernchiroillo and Merlo aquatico of the Italians; Tordo de agua of the Spaniards; Merle d'eau and Aguastre a gorge blanche of the French; Vattera of the Swedes; Poecrois of the Russians; Pontic, in the Swedish, Elargi; Spero, with a white head, and Birkke Engi of the Norwegians; Wasser-amel, Bach-amel, and Der Flodhek.

Water ouzel.
Adult and Young of the Year.

Nest of Water-ouzel. (Yarrell.)
Among Endogenes, the orders Botomaceae, Naladaceae or Fluviales, Pliaceae, Alismaceae, &c, consist entirely of water-plants; whilst one of the largest of the few families into which cryptogamic plants are divided, the Algae, consists almost entirely of plants which live in the water.

In the plant-kingdom, water-plants are distributed into several groups. One of the first divisions that suggests itself in the study of their forms is derived from the composition of the waters in which they grow. Thus we have the plants which grow in stagnant waters, those which grow in the sea, those which grow in the fresh waters inland. Most of the plants which grow at the bottom of the ocean or float in its waters belong to the family Algae, and in the article Sea-Plants we have given an account of their forms.

These plants are divided into branches, and these branches again into sections, which require the influence of salt-water on the soil on which they grow for their production. Thus species of the genera Salsola, Anabasis, Salicornia, and Glauca will not grow but where they can feel the influence of salt-water; hence they have been called plantae salinae. These plants are found not only where the sea washes, but wherever salt-springs find their way to the surface of the earth. There is another group of plants which have their existence confined to the fresh waters of rivers and streams, which receive the sea or on the banks of rivers to which the sea has access. Such are species of Chenopodium, Heliotropium, Vitex, Eryngium, Samolus, and the Mangrove (Rhizophora). These are called plantae littorales, seu maritimae.

There is also the natural order Algae, although by far the most conspicuous specimens belong to the tribes of Exogenous and Endogenous plants. As the sea claims nearly all the species of the genus Fucus and its allies, so the fresh-water plants claim the larger portion of the group. The Conferva and its allies. The genus Ulva [ULVACEA] has its species in both sea and fresh-water. The division of the natural order Algae containing plants resembling the Conferva are called Algae Conferroideae by Harvey, and contain the genera whose dry leaves or shells are those belonging to this division are composed of filaments and are really or apparently articulated; hence some writers call them Alga articulatae. We here subjoin the characters of the principal tribes into which this division of the order is subdivided.

The Ectocarpce are olive-green or green marine plants; their fructification is monocious and the capsules external, and the globules placed between swollen ramuli. It contains many genera belonging to the genera Lamellaria, Plumatella, &c. The genus Styloceramia is closely connected with the preceding; the colour of the species however is never green—mostly red or purple, and sometimes brown. The fructification is double, the capsules and globules being situated on different plants, and not on the same one. The genus contains six genera, one of which is the Griffithia, a plant named after Mr. S. Griffiths, who has done much to advance the knowledge of the order Algae in Great Britain. The most extensive genera in this tribe are Calothamnion and Polysiphonia. Most of the species belonging to these two tribes are natives of the sea, and are found attached to rocks, and to shells, stones, and corallines which are thrown up by the waves. Many of them are also found parasitic upon the larger sea-algae, as the various species of Fucus and others.

The Conferva are for the most part green plants, but sometimes pink or brown; the fructification consists of a granular-coloured internal mass, which assumes various forms.

The genus Conferva, although still containing numerous species, has been much reduced by the formation of new genera. It has however still an indefinite character, on account of the comparatively little attention which the order Algae has received from botanists. The filaments are arched together, and the globules are in the form of a fruit (7), an internal, coloured, granular mass (endochrome). Colour green, rarely purple or orange. The species of Conferva are found wherever there is water. In running streams they are usually found in the stones at the bottom, and are so abundant frequently in streams, ponds and pools as to conceal everything else. Some few of them are found in sea-water, and some on dry land. Some of the species have been found developing new peculiar forms under the influence of the ingredients of different
The WAT 117 The WAT

mineral-springs; and one, the Conferva thermals, is only found in thermal-springs. Under favourable circumstances they sometimes go on developing to an immense extent in lakes or ponds in which they grow. They are generally at first green, but by long exposure to the surface of the water, and are exposed to the air, they become whitish. The rapidity of the growth of these plants is sometimes very extraordinary, and lakes, and even the ocean itself, are covered for several miles with floating masses of Conferva. The water is rendered as clear as glass. Lightfoot says he has seen at Edinburgh a kind of paper manufactured from the fibres of Conferva fructa. The C. aggreopila, globe crow-silk, or moor-ball, is found with its filaments rolled up into the form of a ball, so that it has the appearance of the balls of hair obtained by rubbing the starch in the stomachs of animals. It is an inhabitant of lakes, but is rarely found. It is not fixed to anything, but floats about at the mercy of the waves. It is the same water in which these species are found, that is the clue to the phenomena of the plant.

The genus Hydrodictyon has filaments which form a network with regular polygonal meshes, and viviparous articulations. There is but one species, the H. utriculatum, Common Water-net, which is a rare plant, and found only in the larger streams in England. It is a beautiful plant, forming a tubular net, which floats freely in the water. The meshes of the network are pentagonal or hexagonal, and vary in diameter from half a line to half an inch, and the filaments from the whole inch to three inches long. The plants die off, and are swept away, leaving a part of the stream uninhabited. The genus Mougeotia, named after J. B. Mougeot, a German botanist, has articulated simple filaments, which are finally united by transverse tubes. The endochore is granular, at length forming roundish globules at the point circumscribed with a thin film. The generation of the undivided plants whose filaments are said to unite before reproduction takes place. That this conjugation does take place previous to their granules possessing any reproductive power, in many of the species, there can be no doubt. But the conjugation of certain forms here supposed to be the conjugate group of genera, in which the phenomenon of conjugation does not take place previous to reproduction. These exceptions occur more particularly in the genera Odontes and Stigonema, at the stage of the species of this genus. Stigonema is found in Great Britain, and the most common is the M. genus varia, which is abundant in pools and ditches, sometimes covering a space 30 or 40 feet in diameter, and having a yellowish-green or dull yellow colour. The filaments are branched.

The genus Tyndardia has simple filaments, inoculating by transverse tubes. The endochore is in two roundish masses, which after conjugation unite to form a single globule. The species are found in ponds and ditches, and I do confess that the result is at the bottom of the water, and after a little time rising to the surface, where they form masses varying in size, of a yellowish and yellowish-green colour.

The tribe Oscillatoriaceae is composed of plants which are green or brown in colour, with continuous tubular filaments, seldom branched, though often joined together so as to appear branched. The fructification consists of an infarred mass divided by transverse septa, finally separating into roundish globules, or filaments, like the others, is found wherever there is water, and is more abundant in fresh water than in the sea. There are however many of them found in the sea, and also in mineral-waters. Many of the species, especially of Oscillatoria and Mougeotia, have several species of Os- cillatoria are found in Great Britain; the most common is the endochore, which is transversely striated, and at length circular. The species of Oscillatoria are found only in streams of fresh water, the tubular filaments of which are found derived from the filaments found naturally in springs. There are several genera in the tribe Oscillatoriaceae. Stigonema has cylindrical, cartilaginous, branched, inarticulate filaments, with brown or olive-coloured endochore, which is transversely striated, and at length circular. The species of Oscillatoria are found only in springs of fresh water, the tubular filaments of which are found derived from the filaments that have successively radiated and died in the course of that short period.

There are several genera in the tribe Oscillatoriaceae. Stigonema has cylindrical, cartilaginous, branched, inarticulate filaments, with brown or olive-coloured endochore, which is transversely striated, and at length circular. The species of Oscillatoria are found only in springs of fresh water, the tubular filaments of which are found derived from the filaments that have successively radiated and died in the course of that short period.
stratum of indefinite extent, which is very conspicuous after a shower of rain. Other species are parasitic upon some of the Fucis, and are found in the sea.

The genus Oedogonium is plastic, oscillating, simple, continuous filaments, which are invested by a common mucous matrix. The species are very numerous, but many of them are very difficult to distinguish. They are not all found immersed in water, but always occupy damp places. The T. Oedogonium is an inhabitant of the warm-springs of Bath, occupying broad velvet-like patches of a dark green colour. Its singular appearance, Sir J. E. Smith observes, arises from the filaments being collected together into little ascending tufts, apparently rooted in the muddy deposit of the water. Each tuft proves, on examination, to consist of simple, reniform, even filaments, crowded together, and quite pellucid and equally destitute of joints and branches; their diameter is not more than an eighth or tenth thousandth part of an inch.

The next tribe of the Confervoid Algae is the Bryoideae. These plants cannot be called water-plants, although generally a large quantity of moisture is necessary for their production, and some of them live entirely in water. They are plants of double nature. Their superficial parts are related to many of the Fungi as to the Alge. They have articulated filaments, which are either transparent or coloured. Their fructification consists of granules, which are scattered among the filaments or capsules. They are found in various situations: some on rotten wood, others on glass or in chemical solutions; a few inhabit fresh-water, and one or two the sea. The following genera have been constructed for them. The number of species refers to the number of habitats rather than to the number of genera.

**Byssoscladium.** Filaments arachnoid, radiating from a centre, with scattered external granules. One species found on windows and damp glass.

**Mycentra.** Membraneaceous, opaque, tenaceous, coloured filaments. Four species, all resembling fungi in their characters.

**Chloroptus.** Rigid, subsolid, opaque, erect, minute filaments, falling to powder: with joints, often contracted. Eight species, mostly found on the stems of decaying trees. They are abundantly distributed, on rotten wood, others, on glass or in chemical solutions; a few inhabit fresh-water, and one or two the sea. The following genera have been constructed for them. The number of species refers to the number of habitats rather than to the number of genera.

**Protocenema.** Subarticulated, branched, rootless, mostly green filaments. Five species, found on damp earth, &c., and are suspected to be degenerate or rudimentary mosse.

**Hypoceros.** Hyaline filaments intervoven into a uniform membrane or gelatinous mass. Seven species, few of which have been found more than once, and then in various chemical solutions, as rose-water, solution of murate of barytes, ink, Madera wine. &c.

Lemmna. Hyaline filaments, erect, and parasitical. Three species, one of which is found on fishes and dead flies.

The remaining tribes of Alge which inhabit the water entirely, and about the real nature of which there is still much difference expressed under the name.

The remaining water-plants, with the exception of the less important species, will be found described under the names of their various genera. Nearly all the Confervae live quite under the water, and are called *planta supermersa.* To this same class must also be referred the species of Chara, Naias, and Ceratophyllum. Those which float about and are carried by streams and tides, are called *planta submersa.*

**WATER-RAIL** (Rallidae, vol. xix., p. 283.)

**WATER-SPANIEL.** (Spaniel.)

**WATER-SPOUT.** (Spout, Water.)

**WATER-WAGTAIL.** (Wagtail.)

**WATER-WHEELS.** (Hydraulics.)

**WATER-WORKS, WATER-PIPES.** In an extended sense the term water-works is applied to all machineries and engineering works for the purpose of raising, retaining, conducting, or distributing water, and also to contrivances for obtaining motive power from falls or current of water. Some of the sluices, fountains, pumps, water-wheels, and hydraulic engines generally; but as many of these are treated elsewhere, the chief object of the present article will be to notice the contrivances employed for the collection, purification, and distribution of the supply for the purposes of navigation or manufacturing purposes, referring to AQUEDUCT, CANAL, EMBANKMENT, SLUICE, FOUNTAIN, TANK, SEWERS, DRAINING, IRRIGATION, and HYDRAULICS, for information on other subjects embraced under the several denominations.

The importance of an ample and regular supply of pure water for domestic purposes, especially in large towns, where the rapid accumulation of filth of every kind renders frequent abolition of the person and apparel, as well as of houses and streets, essential to the preservation of health, is too strongly insisted on; especially as, notwithstanding the extent and comparative excellence of the means employed in this country for affording it, the poorest and most crowded districts of our large towns are often lamentably unacquainted with the principle, so important in modern water Works, by which water will find the same level at the two ends of a continuous pipe, unless prevented by confined air or some other impediment, notwithstanding any depressions or changes of level in its intermediate courses; and, as shown in these reports, p. 388, this assertion is incorrect. The want of suitable materials for pipes of large capacity, when exposed to the pressure of a head of water, is sufficient to account for the fact that they did not attempt, on any important scale, to distribute water for domestic purposes, until the great supply from an elevated source, conducting it by a nearly uniform and moderate slope to the point where it was delivered for use. In order to effect this, they erected costly aqueducts across such valleys as it was necessary to cross, and, as mentioned under AQUEDUCT, vol. ii., p. 204, they were sometimes compelled to conduct them in a serpentine direction, in order, by increasing their length, to render the slope sufficiently moderate. A list of the aqueducts built up to the present time is given in the Reports of the Committee of 1855, vol. xx., p. 102; and under FOUNTAIN is a notice of the arrangements adopted by the Romans for distributing the water brought to the city by them.

The modern engineer, instead of being compelled to erect such gigantic works to convey a current of water from one place to another, has the means of providing for the wants of a whole town without any official stream, is enabled, by the possession of materials suitable for the construction of pipes of any required size and strength, to convey a current of water in any direction, and to vary its level according to circumstances, raising or lowering it at will, and facility in the provision of the highest portion of his pipe be somewhat less than that of the reservoir from which the supply is drawn. The same circumstances, coupled with the command of unlimited moving power for the propulsion of water along a scale of works, enable line of water to be distributed at a higher level than the source whence the water is procured, or even to supply a town or district entirely
with water taken from a lower level. Referring to Hydrodynamics, vol. xii., p. 369, for the means of determining the necessary size for delivering a given quantity of water at any required distance, under given circumstances of direction and pressure or head of water, we proceed to notice a few of the points involved in the construction of such water-works as have for their object the convenient distribution of water for household purposes.

The most simple case for the construction of water-works is that where the source of supply is situated at a greater elevation than the points at which water is required to be delivered. In such a case, unless there be a natural reservoir of sufficient capacity, one or more must be formed artificially, being rendered water-tight by puddling or other means, and from this reservoir large pipes, or mains, are led by the water into the principal parts of the town. Branch pipes, opening into the larger mains, are added to convey the water into the minor streets, and smaller leaden service-pipes, each having a stop-cock to prevent the escape of water when not required, complete the distribution of the water into individual habitations. When the supply of water at the original source is plentiful, no further apparatus is necessary, as the mains may be kept continually charged, and consequently water will flow from the service-pipes whenever the stop-cocks are opened; but where the water is not so abundant it may be distributed more economically by a provision for closing the passage of some of the mains, dividing the town into districts, and allowing the mains in one district to be charged at one time, and those of another district at another time. This arrangement involves the necessity of using cisterns or butts in connection with the service-pipes, which may be filled with the water while the mains are charged, and form small reservoirs for the use of individual households during the time in which the water is diverted to another part of the town. In this case the service-pipe, instead of being fitted with a stop-cock to turn by hand, has a self-acting cock or valve, usually of the construction called a ball-cock, which is a cock having on its upper end a ball that will float up and stop the passage of water at the end of which carries a thin copper ball of four or five inches diameter. The whole is so fixed that when there is little or no water in the cistern the weight of the ball causes it to descend as far as a fixed stop attached to the axis of the cock will allow it, and thereby to open the cock ready for the admission of water whenever it may be turned on to the main; but so soon as the cistern becomes filled to a certain height, the buoyancy of the copper ball causes it to rise with the surface of the water, until it has turned the axis of the cock and prevented the inflow of any more water, when it of course remains stationary until the gradual sinking of the water, as it is drawn off for use by the ordinary stop-cock attached to the cistern, allows it again to be turned by hand to open the cock for fresh supply. Ingenious as this arrangement is, it is very liable to breakage, and a little stiffness in the working of the cock, such as may arise from remaining out of use for a time, occasions its action to fail, and either prevents the admission of water at the proper time, or, more commonly, allows the cock to remain open after the cistern is filled, and so causes serious inconvenience and waste of water. To remedy this, several plans have been proposed. Hebert (Engineer's and Mechanic's Encyclopedia, vol. ii., p. 852) mentions a very simple contrivance by which a float connection with the end of the service-pipe is turned vertically downwards, and terminates in a valve-seat, into which a valve is raised by the action of a float connected with it by a vertical rod. This does not however appear to be so effectual as the contrivances in which leverage is employed to aid the action of the valve, or those in which the pressure of the water in the service-pipe is employed for the same purpose. A very ingenious apparatus of the former kind, contrived by Mr. Crockett, is described in the 52nd volume of the Transactions of the Society of Arts (p. 54). It also has a vertical valve, which rises upwards against its seat by a lever connected with a hemispherical copper float; but it is distinguished from other

ball or float-valves mainly by the addition of a ratchet and click apparatus which retains the lever and float in the lowest position to which the substance of the water allows them to fall, and consequently keeps the valve fully open, until the water rises to the required level, when, by the buoyancy of a second and smaller float, the click is released so that the main float rises, and closes the valve. As the main float is, when the cistern is fully charged, entirely submerged, the whole of the power derivable from its buoyancy is applied to the closing of the valve. This apparatus has the merit of working in a smaller vertical space than most others, so that it is well adapted for shallow cisterns; but while it is perhaps the most perfect contrivance of its kind, it is too complicated for general use. Referring the reader to the volume above cited for a fuller description, with cuts of the apparatus, we therefore proceed to describe a more simple and very effectual contrivance invented by Mr. Bullock, of which there is an account in the thirty-eighth volume of the same work (p. 57). Fig. 1 is a representation of this apparatus a being a bent tube, the upper extremity of which is tapered for insertion into the end of the leaden service-pipe, and which has at its lower extremity a curved bar b, to support the fulcrum of the lever c d e. The tube is represented in section, in order to show the form of the inverted conical valve, which is raised so as to allow a free discharge of water from the pipe. The separate figure f shows the form of the opening at the lower end of the tube a, with the ring which serves as a guide for the vertical stem or tail of the valve, and also the form of the bar b; and at g is a separate representation of part of the lever, showing the form of the swivel-joint by which it is attached to b: b has two shallow holes, which receive the points represented in the separate figure g; and the joint may be made tighter or looser at pleasure by turning the thumb-screw d, which carries one of the swivel-points. When the cistern is nearly full, the ball c is borne up by the water, and consequently the shorter end of the lever falls, allowing the valve to descend by the combined action of its own weight and the pressure of the water above it. In another float-valve on the same principle, contrived by Mr. Magson, and described in the forty-fourth volume of the Society's Transactions (p. 50), the fulcrum of the lever is placed immediately below the valve, and the shorter arm of the lever is curved in such a way as to increase the efficiency of its action. Fig. 2 represents, on a larger scale than the preceding cut, the most important part of this apparatus; the valve and lever being left white to distinguish them from the stationary parts. The valve is shown open, as it would be when the float is depressed; but the dotted lines show the position of the lever when the float is elevated, and the valve is allowed to fall into its seat. The float con-
side of a flat round piece of wood, which may be attached to the long arm of the lever simply by a screw, or better by a joint which will allow it always to assume a horizontal position, whether the lever be raised or depressed. In addition to its greater certainty of supply, the valve will also admit the supply of water into a cistern in half the time required by the common ball-cock; that it effects a saving of twenty-five per cent. in first cost; and that, as it is made of cast-iron, it does not afford the same temptation to pilferage, inasmuch as it has no brasses or copper. Mr. Magson’s valve had been found to act satisfactorily under the pressure of a column of water of more than seventy feet. In the same paper is described an improved stand-pipe, with a valve of the same character as that just described, which has been in common use in many water-mains, and private service-pipes are rendered useless by ice. The common stand-pipe is simply a wooden pipe inserted into a plug-hole connected with the main, and fitted with a faucet and spigot, or sometimes with a common cock; but as such pipes, when set up in a common street, are very liable to be left open from carelessness or mischief, thereby occasioning a waste of water, and the formation of ice which renders it dangerous to approach them. Mr. Magson’s valve is constructed in such a manner that, while pressure is applied to the handle of a bent lever which lifts the tail of the valve. Such a contrivance might be useful in many other cases, since it renders the accidental escape of water impossible.

The pumps most frequently referred to the means of supplying a town with water from a source situated at a higher level than the points at which the water is to be delivered; but it frequently happens that considerabld districts, and sometimes, when the water is obtained from a river flowing through another nation, it is necessary to be supplied, as the pipes extend, lies at a higher level than the source. In this case the most usual course is to contract one or more reservoirs at a suitable elevation, and to supply them with water through ascending pipes or mains from the force-pumps. In this way the steam-engine forms the principal source of power. The reservoirs may, in such cases, be formed upon elevated ground, or, in the absence of any more convenient site, upon the tops of high buildings; and from them the distribution is effected in the same way as when the water is originally obtained from a level source.

Sometimes also it is desirable to supply houses at a higher level than the most elevated reservoir, and this object may be effected either by employing a separate pumping-engine to propel the water from the reservoir to a point in the main which lies at a higher level in the ordinary way; or, in some cases more economically, by closing for a time the passage between the reservoir and the force-pumps by which it is supplied, and opening a connection between the ascending mains and the high-service pipes. To prevent the danger which might arise from the application of too great a pressure by the pumping-engine, a vertical pipe, sometimes called a ‘standing-pipe,’ should be connected with the pipes for the high delivery, and carried up to an elevation equal to that of the highest point to be supplied. This pipe, which may be erected in the reservoir, and left open at the top, or turned downwards again in the form of a siphon, acts as a safety-valve to the whole system, and allows the water to overflow when too much pressure is produced. By this means the saving the mains from the danger of bursting. In some situations such standing-pipes may be objected to as unsightly, and in others they may prove inconvenient or dangerous, from their attraction for the electric fluid. The safest means for avoiding this is to provide water loaded to a degree equal to the pressure of the required column of water, an improvement which has been carried into effect by Mr. Simpson at the reservoir of the Chelsea Water Company in Hyde Park, and in some other places. The same mode of propelling water along the ordinary mains and service-pipes by means of force-pumps, instead of causing it to flow along them by the hydrostatic pressure of an elevated reservoir, is sometimes adopted to a considerable extent in supplying a town directly from a river or other low source.

The repeated investigations by commissioners and par-
lamentary committees, especially within the last fifteen years, into the state of the supply of water to the British metropolis, and the various means suggested for its improvement, have elicited much curious and valuable information. It is stated that in the use of Thames water, it must be admitted that whenever a river is exposed to the impurities consequent upon the drainage of an extensive and densely inhabited district, every precaution should be observed in taking water for the appliance of the mains from situations the least exposed to vitiating causes, and every practicable means should be adopted for removing such impurities as may be pumped up with the water, before it is distributed for use. The tide-water, suggested a means of avoiding these evils, by such of the metropolitan water companies as derive their supply from the Thames, of measures by which the water of that river is rendered unobjectionable for all practical purposes, and it is worthy of recollection that with all the changes that have been wrought in the use of Thames water, it has been seriously felt by the New River Company during severe winters; and it has been urged by way of objection to some plans for supplying part of the metropolis with water brought from a considerable distance in other open channels, that the Thames, by its great depth, is not likely to be affected, either in quantity or quality, by the vicissitudes of droughts and floods, and least likely to be obstructed by ice, than can be obtained from minor streams, sometimes exposed to pollution from the nuisance which it is impossible for the Konstruct of the land required for their construction, the water is liable to impunity from the banks being washed down by rain, or trodden in by cattle, and from the stream being used for washing dogs, the nuisance which it is impossible for the construction of a subterraneous channel or tunnel, six feet in diameter, with a sufficient slope to cause the water to flow freely along. The channel proposed by Mr. Taylor was to be nine miles and a quarter long, commencing for the first mile at Southwark, and terminating under Hampstead Hill, the summit of which is 437 feet above low-water mark at Hammersmith; and reservoirs were to be formed on the surface at the end of the aqueduct, and at any other elevated points from which it might be desirable to distribute the water, which was to be raised into them through vertical shafts by steam-pumping-engines. By this means the power of the steam-engine should be applied much more economically than in the usual method of forcing water through a great length of iron piping, up inclined planes, and frequently along a tortuous course. The friction and resistance thus occasioned is so great that, according to Mr. Taylor’s calculations, engines depending upon a height of forty feet would not amount to more than fifteen millions of pounds one foot high for every bushel of coals consumed, while a duty of seventy-four millions of pounds per bushel had been attained by some of the Cornish steam-engines employing the sitarg engine by such engines, and the saving the mains from the danger of bursting. In some situations such standing-pipes may be objected to as unsightly, and in others they may prove inconvenient or dangerous, from their attraction for the electric fluid. The safest means for avoiding this is to provide water loaded to a degree equal to the pressure of the required column of water, an improvement which has been carried into effect by Mr. Simpson at the reservoir of the Chelsea Water Company in Hyde Park, and in some other places. The same mode of propelling water along the ordinary mains and service-pipes by means of force-pumps, instead of causing it to flow along them by the hydrostatic pressure of an elevated reservoir, is sometimes adopted to a considerable extent in supplying a town directly from a river or other low source.

A Brief Description of the various plans that have been proposed for supplying the metropolis with fresh water. [Page, London, 1851]
effecting a saving to the company of three-fourths of the fuel previously expended.

In some of the schemes for improving the metropolitan supply, it has been proposed to obtain water from the Thames at or above Teddington Lock, or to remove the lock now situated at Teddington to Richmond, and to take the supply from the portion of the river which would then be cut off from the influence of the tides; but in addition to the expense of an artificial aqueduct, whether open or covered, of the length necessary for such a scheme, it would have the disadvantage of injuring the navigation by the abstraction of a large portion of the water.

In Mr. Martin's plan for bringing water from Teddington Lock, it was proposed to raise the weir so as to give it a fall of six feet, and to erect water-wheels at the weir, by which the power of the water would effect an elevated reservoir in Richmond Park, from which it should be conducted in large pipes, either under or over the surface, to Earl's Court, between Kensington and Brompton, where the pipes of the various companies which supply the western part of London should receive their respective supplies from the aqueduct.

In addition to plans for obtaining water from the upper part of the river Thames, or from minor streams, such as the Colne, the Verulam, and the Wandle, various schemes have been proposed for extensive reservoirs by embanking or sinking wells in or in the immediate neighbourhood of London. In some of these it has been proposed to sink wells or tanks of considerable depth near to the banks of the Thames; but as the greater part of the water entering such tanks is received with the water entering the river, such a plan offers few, if any, advantages for general adoption beyond that of purifying water which has been taken directly from the river by allowing it to settle so as to deposit the greater impurities and then causing it to pass through a filter. Some of the kind has however been done successfully by the West Middlesex Water-works Company, who have formed extensive reservoirs on the banks of the river at Brentford, which, though at high-water, forces a quantity nearly sufficient for one day's supply through the gravelly bed and bank. A floodgate opening into the upper part of the reservoir affords the means of admitting a supply direct from the river, when required.

Proposals for supplying the metropolis from wells bored to such a depth, and in such situations, as to be wholly independent of the Thames, have attracted much attention. The object proposed by such bores is to obtain water from the strata of the bed of the Thames below the impervious London clay, such water being originally collected at the points where the pervious strata rise to the surface at the boundaries of the great basin in which the metropolis is situated. Artifical water-holes with a vertical bore, as explained by Mr. New Walks, vol. ii. p. 412, it will be sufficient to refer to the question whether the supply obtainable from them would be sufficient in quantity for the use of the whole metropolis, or even of any considerable portion of it, a point which has been shown to be doubtful.

Mr. Webster, in a course of lectures delivered at the Russell Institution in 1839, after advertising to other cases of failure in the sinking of Artesian wells, and to some in which the sinking of one well has drawn water from another in its vicinity, thereby proving that the supply from the pervious strata is far from unlimited, alluded to an experiment made by the New River Company, who sunk a large shaft or well at their reservoir in the Hampstead Road, and, after being connected with iron pipes, and the stratum of sand and water, and sinking to the chalk below, at a total expense of about 12,000l., could not obtain more than 650,000 gallons of water per week, and were only able to keep their pumps for raising it at work one week in seven.

...
including the cost of the pipes and lead, and making good the roads, was about 8s. per yard; and the whole of the works required in connection with the change in the mode of obtaining a supply of water by this company was nearly 200,000l. From the reservoirs at Paddington, which are cut in the Sarsen stones of Westminster, and which has not been attacked by currents of water from the bed of the river, and from which the water is distributed to the districts supplied, with the assistance of additional engines. In addition to the above-mentioned works, the company stated to the committee of 1840 that they were preparing means for filtering their water before delivery.

The West Middlessex Water-works Company, who, likewise supply part of the western districts of the metropolis, have also, since the year 1834, formed some extensive works for the improvement of their supply, consisting in the construction of a large reservoir near the mouth of the Thames, immediately opposite to the site of the proposed new bridge, and which has been alluded to in a previous column, and in which the water is allowed to settle and deposit its grayer impurities before it is conveyed across the bed of the river, by a conduit resembling that of the Paddington company, to the engine-house at Hammersmith.

The proprietors of the Chelsea Water-works have also expended upwards of 60,000l. in measures for improving their supply, which is taken from the part of the river known as Chelsea Reach, and is supplied in large reservoirs on the south side of the river. In order to avoid contamination by the sewage, which enters the river near the point where their dolphin, which was formed of brickwork and surmounted by a perpendicularly iron structure, was formerly situated, this Company erected a large reservoir of several pipes to the right-hand side of the river for a distance of several miles receives no pollution beyond that occasioned by land-drains. On the south side of the river the Vauxhall Company obtains water of great clearness and purity from beneath the third arch of Vauxhall Bridge, a point which has been observed by watermen for its gravelly bottom, which is remarkably free from mud and sediment. From its establishment in 1806, this company has possessed extensive settling reservoirs near Kennington Lane; and in 1831 arrangements were made for conveying the water partly through the Lambeth works and partly from the Thames at a point a little above Waterloo Bridge, opposite to the works of the company in the Belvidere Road; but it is pumped from those works to an elevated reservoir at Brixton, where a large tank was installed about 1834 in providing means for its purification by subsidence and filtration.

By the above-mentioned improvements, and others effected by companies or companies on the same or different principles, the purity and probably the quality of the London water have been materially improved. It is of a clear, soft, and agreeable taste, is a considerable improvement, and is now fit for drinking without previous distillation or fermentation. It may be further improved by the addition of a very slight proportion of soda or of any of the common drinking-water salts. It is not generally of a good quality, being frequently alkaline, and sometimes it contains an unduly large proportion of certain impurities. It is a common practice to pass through it a current of air, which dissolves the carbonic acid and preserves the water in a gaseous state. The London water is not, however, free from various impurities. Among the more important of these are:

1. Silt and mud, which are removed by filters or sedimentation basins.
2. Algae, which are killed by chlorination.
3. Iron, which is precipitated by adding lime or other conditioning agents.
4. Manganese, which is oxidized in air.
5. Copper, which is precipitated by adding lime or other conditioning agents.
6. Lead, which is precipitated by adding lime or other conditioning agents.
7. Silver, which is precipitated by adding lime or other conditioning agents.
8. Zinc, which is precipitated by adding lime or other conditioning agents.
9. Arsenic, which is precipitated by adding lime or other conditioning agents.
10. Fluorine, which is precipitated by adding lime or other conditioning agents.
11. Bacterial and viral pathogens, which are killed by chlorination or other disinfection processes.
12. Heavy metals, which are removed by filtration or precipitation processes.
13. Organic pollutants, which are removed by coagulation and sedimentation processes.
14. Pesticides, which are removed by filtration or adsorption processes.
15. Nitrogen compounds, which are removed by filtration or precipitation processes.
16. Phosphorus compounds, which are removed by filtration or precipitation processes.
17. Fluoride, which is precipitated by adding lime or other conditioning agents.
18. Arsenic, which is precipitated by adding lime or other conditioning agents.
19. Chloride, which is removed by filtration or precipitation processes.
20. Nitrite, which is removed by filtration or precipitation processes.
21. Nitrate, which is removed by filtration or precipitation processes.
22. Sulfate, which is removed by filtration or precipitation processes.
23. Carbonate, which is removed by filtration or precipitation processes.
24. Bicarbonate, which is removed by filtration or precipitation processes.
25. Sulfide, which is removed by filtration or precipitation processes.
26. Alkalinity, which is removed by filtration or precipitation processes.
27. Acid, which is removed by filtration or precipitation processes.
28. pH, which is adjusted by adding lime or other conditioning agents.
29. Temperature, which is adjusted by cooling or heating.
30. Odor, which is removed by filtration or precipitation processes.
31. Taste, which is removed by filtration or precipitation processes.
32. Chloroform, which is removed by filtration or precipitation processes.
33. Trichloroethylene, which is removed by filtration or precipitation processes.
34. Tetrachloroethylene, which is removed by filtration or precipitation processes.
35. Volatile organic compounds, which are removed by filtration or precipitation processes.
36. Nitrates, which are removed by filtration or precipitation processes.
37. Nitrites, which are removed by filtration or precipitation processes.
38. Ammonium, which is removed by filtration or precipitation processes.
39. Dissolved oxygen, which is removed by filtration or precipitation processes.
40. Dissolved carbon dioxide, which is removed by filtration or precipitation processes.
41. Dissolved nitrogen, which is removed by filtration or precipitation processes.
42. Dissolved phosphorus, which is removed by filtration or precipitation processes.
43. Dissolved silica, which is removed by filtration or precipitation processes.
44. Dissolved calcium, which is removed by filtration or precipitation processes.
45. Dissolved magnesium, which is removed by filtration or precipitation processes.
46. Dissolved iron, which is removed by filtration or precipitation processes.
47. Dissolved manganese, which is removed by filtration or precipitation processes.
48. Dissolved copper, which is removed by filtration or precipitation processes.
49. Dissolved zinc, which is removed by filtration or precipitation processes.
50. Dissolved lead, which is removed by filtration or precipitation processes.
51. Dissolved silver, which is removed by filtration or precipitation processes.
52. Dissolved cadmium, which is removed by filtration or precipitation processes.
53. Dissolved chromium, which is removed by filtration or precipitation processes.
54. Dissolved arsenic, which is removed by filtration or precipitation processes.
55. Dissolved selenium, which is removed by filtration or precipitation processes.
56. Dissolved molybdenum, which is removed by filtration or precipitation processes.
57. Dissolved vanadium, which is removed by filtration or precipitation processes.
58. Dissolved nickel, which is removed by filtration or precipitation processes.
59. Dissolved aluminum, which is removed by filtration or precipitation processes.
60. Dissolved cobalt, which is removed by filtration or precipitation processes.
61. Dissolved cobalt, which is removed by filtration or precipitation processes.
62. Dissolved cobalt, which is removed by filtration or precipitation processes.
63. Dissolved cobalt, which is removed by filtration or precipitation processes.
64. Dissolved cobalt, which is removed by filtration or precipitation processes.
65. Dissolved cobalt, which is removed by filtration or precipitation processes.
66. Dissolved cobalt, which is removed by filtration or precipitation processes.

120. Dissolved cobalt, which is removed by filtration or precipitation processes.
of fermentation takes place in the water when it is in contact with the sand, especially when moss or other vegetable matrices are present in any considerable quantity, by which the water is greatly purified, while a very perceptible film is thrown up to the surface. By the works above described, from 400,000 to 500,000 cubic feet of water are filtered every day.

The antiseptic properties of charcoal render it a very effectual, though costly, filtering material. Animal charcoal has been applied in France as a purifying medium in portable filters, in which it acts well, though the percolation of water is slow. As has been previously remarked, it has been partially practised with the water of the Seine at Paris. A plan of charcoal filtering is proposed in the appendix to the little work referred to in a note on a previous column, which appears well adapted for use upon a small scale, and might be applied in cases where the filtering bank or embankment, on one side of which is the water to be purified, and on the other the reservoir of filtered water, and the charcoal is disposed in the form of a thick wall, with vertical sides, enclosed by a framework of timber, and performed by placing the finest portion of the charcoal in the centre, and so cover the top of the wall or embankment with moveable planking, by opening which the charcoal might be removed and renewed at any time without deranging any other part of the arrangement. The charcoal is thus placed in the filtering bank or embankment, on one side of which is the water to be purified, and on the other the reservoir of filtered water, and by maintaining the same地位, it is proposed to pass through them before coming into contact with the charcoal. This inclined position of the surface of fine sand would occasion the heavier impurities to slide towards the bottom of the slope, whence they might be removed as often as necessary. It should be observed, that as the fine sand which forms the uppermost layer would, at the top of the slope, lie in immediate contact with the planking, the planks should be close-jointed and left without perforations at the bottom, lest the impurities they contain should pass through before coming in contact with the charcoal.

This inclined position of the surface of fine sand would occasion the heavier impurities to slide towards the bottom of the slope, whence they might be removed as often as necessary. It should be observed, that as the fine sand which forms the uppermost layer would, at the top of the slope, lie in immediate contact with the planking, the planks should be close-jointed and left without perforations at the bottom, lest the impurities they contain should pass through before coming in contact with the charcoal.

The works above described, from 400,000 to 500,000 cubic feet of water are filtered every day.

For the watering of roads, and some other purposes for which large quantities of water are required, it is unnecessary to go to the expense of a perfect system of filtration, excepting where, for ornamental purposes, the supply must be conveyed through the same pipes as those conducting pure water for domestic use. Since the increasing extent of the supply afforded by the Chelsea Waterworks Company made this consideration a matter of much importance and utility, the following plan was submitted to the supply of the basin in Kensington Gardens, the Serpentine River, and the other ornamental waters in Hyde Park, St. James's Park, and the gardens of Buckingham Palace, connecting also with these works the supplies for watering the streets and roads in their district. This water for these purposes is obtained from a large land-spring well in their works on the bank of the Thames, assisted by river water thoroughly filtered. This measure has, we are informed, proved a highly important one, as it relieves the mains by preventing the clogging of the pipes, and the smaller ones to which they were subjected during summer for watering the roads, especially as this supply was required during the day-time, when it is of consequence that water-companies should direct all their powers to the supply of drinking water. Another demonstration of the excellence of this plan, inasmuch as it leads to a continual change in those ornamental waters which would otherwise be unhealthy stagnant pools. The Serpentine has been much and reasonably complained of on this ground, its supply having been formerly derived from a stream which in course of time became a common sewer, while, since that nuisance has been destroyed by diverting the sewer, its level has been frequently much reduced by evaporation in a dry season, by which it has been reduced to a state by no means calculated to benefit the health or gratify the senses of the frequenters of the park, and especially of those who make use of it for bathing. The water-companies are now allowed to take any quantity of water from the Serpentine, provided that they do not divert it to a purpose other than the supply of water to it through the Kensington Basin. This they frequently do to the extent of 500 tons daily, which, together with the supply taken by government, whom the Serpentine belongs, and the water companies of the roads and malls in St. James's and the Green Parks, occasion a circulation highly favourable to the salubrity of this sheet of water.
manner by enlarging the bore in a conical form at one end of the pipe, and hewing the end of the adjoining pipe into a taper form so as to drive into the conical cavity. To prevent the socket end of the pipe from bursting by the force applied in hammering up this joint, an iron hoop was employed, fixed on to it. A thin earthenware conical water-tight at first, which was by no means easy, speedily became defective from the decay of the wood forming the thin or spigot end of the pipe. Perhaps the best method of connecting wooden pipes is that in which the bore is enlarged at one end to the size of the cavity at the other end of the pipe and the connection is formed by a short iron tube, cast externally into the form of a double cone, and driven into the adjoining ends of two lengths of wooden pipe. Among the schemes which have been proposed and tried to a limited extent for avoiding the defects of being protected, to conduct water in a state of greater purity than in those formed of cast-iron, are the use of wooden pipes formed of staves, fitted together and hooped like barrells; of stone pipes, for the formation of which very ingenious machinery has been contrived, capable of cutting several concentric pipes out of a single block of stone by the operation of a series of saws somewhat resembling those known as fregon saws (Saw-Mill, Fig. 6, vol. xx., p. 461); or, in a kind of patenting the wood, which excels others for keeping water perfectly pure, and which may readily be fashioned into a form convenient for joining, the difficulty of which is a serious objection to stone pipes. To obviate the objection to earthenware pipes, and their fragility, has been proposed, to use pipes lined with pottery, but formed externally of wood or iron.

While this article is in the press, the newspapers announce the manufacture, in France, of water-pipes formed of coarse glass, and proved externally, to withstand water-bitsmens. These are joined together with bitsmen, in a similar way to the lead or cement used with common iron pipes, and they are said to be considerably cheaper than those of cast-iron, and capable of sustaining a greater pressure.

While however other materials are used advantageously employed to a limited extent, and under peculiar circumstances, cast-iron is the only material at once sufficiently strong, strong, and manageable, or convertible into the required forms, for extensive water-work purposes. Pipes of this material are cast, usually in lengths of from eight to ten feet, of any required size, from a few inches to three feet or upwards in diameter; and every variety of curved or angle pipes, pipes with fire-plugs, &c., can be readily furnished. These pipes are connected together by flanges connected by screw-bolts, with an intermediate packing of lead or other soft substance; but this plan is not suitable for adoption to any considerable extent, as it makes a large portion of the alteration of length occasioned by the expansion and contraction of the metal. The usual plan, both for large and small pipes, is to cast an enlarged socket at one end of each length of pipe, to receive the other or smaller end of the adjoining pipe, which is cast with a slightly tapering angle at each end. In noticing, on a previous column, the works of the Grand Junction Company at Brentford, a mode of connecting such pipes without packing has been described; but the more general practice is to run lead into the joint, so as to fill up the cavity left in the socket after the spigot end of the pipe has been inserted, a gasket having been previously inserted and driven tight all round to prevent the lead from running into the pipe, and a temporary clay mould being applied to the collar; or, to effect the same object by caulkling with hemp and iron cement, which is a mixture of iron borings or turnings with sulphur and sal-ammoniac, moistened with water as it is rammed in. By the subsequent oxidation of the particles of iron, this composition iconcists into a solid body, and forms a very secure joint. Roman cement has also been used for this purpose. Another mode of securing the joints of iron-water-pipes, which appears to present many advantages, is by the application of a series of wooden wedges to fill the cylindrical cavity of the pipe, in a paper communicating with Mr. Thomas Wicksteed, engineer to the East London Waterworks, to the Transactions of the Society of Arts (vol. ii., part ii., p. 50, for the session of 1836-7), it is stated that such joints have been successfully employed for forty years at the Norwich Waterworks, and for more than half a century in the collieries near Newcastle on Tyne, and that they had been

found both cheaper and better than joints secured with lead or cement. The East London Waterworks Company had, at the date of Mr. Wicksteed's communication, used these joints for seven years with the most favourable results. With regard to their durability, in addition to the well-known metal they are protected, as it is in these joints, from the action of air and water, evidence is adduced of their having remained perfectly sound for fifty years; and it is stated that all those made by the East London Company during five years had stood, in all, without having been ruptured or leaked. They had then 38,558 yards, or nearly 22 miles, of piping laid with wooden joints, the diameter of the pipes varying from three up to eighteen inches; and the repairs had cost much less than with lead or cement. To obviate the objection of such a joint being blown out under a great pressure, Mr. Wicksteed tried joints in pipes of three different diameters under a proving machine, increasing the pressure until it became equal to a column of water 723 feet high, without affecting the joints; and he states that at that pressure merely for fear that the apparatus might give way. The pipes were, respectively, three inches diameter and three-eights of an inch thick, five inches diameter and half an inch thick, and eighteen inches diameter with a thickness of barely three-quarters of an inch; and Mr. Wicksteed believes that they would have burst before the joints could have given way.

The wood recommended for forming the wedges is the best man of English or American oak, or perhaps beech, the cut is to make into chocks nine inches long, which are to be riven with an axe into pieces about two inches wide and three-quarters of an inch thick. These pieces are then worked with spokeshaves into the proper curved form, one side being hollowed to fit the outside of the pipe, and the other rounded into a convexity fitting the inside of the socket; and they are made to taper slightly from the middle towards each end, so that when cut transversely in half they form two wedges of four inches and a half long. These wedges are in the first place driven into the pipe with the wedges, and are placed in the vousoirs of an arch, and driven in by a set applied to their external ends in succession, the wedges being thus driven in gradually all round, as a cooper hammers on a hoop. When fully driven in, if any of the ends project, they are cut off with a handsaw. When the work has been made as many joints as may be required to allow time for filling up the trench and covering in the pipes at the close of the day's work, a bonnet is strapped on to the end of the newly laid line of pipe, and water is allowed to run so as to try the joints under the pressure of the mains; or, in new works, where there is no connection with charged mains, under the pressure of a force-pump. The joints are then carefully examined, and wherever any leakage is discovered or the joint may be thought defective, it is allowed to drain dry, and a wooden spile is driven in to tighten the wedges. The subjoined cut (Fig. 3) gives sectional representations of a joint secured with wooden wedges, the end view showing the manner in which spiles may be inserted at the junction of the wedges.

![Fig. 3](image-url)

Where it is necessary, in order to accommodate slight changes of direction in the road, to make joints a little out of the straight line, wedges are inapplicable, and the or ordinary joint is made by a bend or a curve at any jointing at a curvature of about a quarter of a circle. Mr. Wicksteed conceives that the elasticity of the material gives it a firmer hold on the joint, and consequently renders it less liable to be blown out than either lead or cement; and he mentions, as disadvantages of the latter, that it required time to make with a chisel, none being applied; and that if it should fail, the joint must be made entirely fresh, as it can neither be spiked, like a wood joint, nor set up, like one filled with lead. To show the economy of the system recommended, he gives a table of the relative cost of wood, cement, and lead joists for one
An ingenious flexible iron main was contrived by Watt, in the form of what is known as a coiled or corkscrew, a supply of pure water across the bed of the river Clyde, for the Glasgow Waterworks Company, which, by the occasional introduction of a kind of ball and socket-joint, is enabled to adapt itself to the uneven surface on which it lies. The iron pipe is laid upon long frames or beds of timber, with moveable joints corresponding with those of the main itself; and the laying of the whole in its assigned place was effected by hauling or dragging it from one shore to the other, the end of the pipe being, of course, plunged up during the operation. The pipes may be the common, 3 inches diameter, and as it was found to answer the desired end very satisfactorily, and a greater supply of water became necessary, after a few years a second was added, eighteen inches in diameter. A full description of the conveyance of water to Glasgow is given in the "Edinburgh Philosophical Journal," vol. iii., p. 60.

When the use of cast-iron pipes for water was first becoming common, much prejudice existed against them, on the ground that, while they were very expensive to purchase, they would eventually prove erroneous, that they would deteriorate the water conveyed through them. A slight degree of oxidation takes place at first, but after a thin crust has thus been formed on the surface of the iron, it affects the water no further, at least not in a perceptible degree. It has been asserted that water which contains lime deposits, when passing through iron pipes, a crust which defends the iron from corrosion, and which will not increase beyond a moderate thickness; and this discovery has been usefully applied by sending limes, that is, water to which lime is added, to form such a crust artificially, when corrosion has been found to take place to such a degree as to render the water unpleasant.

Lead, from the facility with which it may be manufactured, formed one of the earliest materials for water-pipes, having been employed by the Romans as early as a very early period in the history of modern waterworks. For large pipes it has been entirely superseded by cast-iron; but it is still employed for the small branches or pipes by which the house is supplied, for which purpose its pliability renders it admirably adapted, as it is frequently found in England necessary to be conducted in a tortuous and angular course, in order to conceal it as much as possible where they pass through kitchens, &c. Any joints that may have to be made in the pipes, when laid in the ground, or in joining the pipe to a cock, cisterns, &c., are effected by soldering; the surfaces to be united being made perfectly clean and bright, and the parts being held or fastened together, while the plumber pours the solder upon the joint, holding a pad made of tallow beneath the part to prevent the liquid solder from falling to the ground. This operation must be frequently repeated before the lead becomes sufficiently hot to take the solder; and when it begins to take effect, the workman continues patting and work, not to make the joint so tight as to keep it held in his hand, to keep it uniformly about the joint. A soldering-iron may be applied to facilitate the operation as soon as the solder begins to adhere; and a considerable body of solder is left round about, forming a lining, a thickness being collar. In soldering pipes laid in the ground, as the operator cannot look directly at the underside of the pipe, a small mirror is employed, to enable him to see when the joint is perfect. It should be borne in mind, in using lead pipes, that their want of elasticity renders them unfit for employment to convey water impelled by the strokes of an engine-pump, because the impulse communicated by the pump causes the pipes to swell, and they do not return to their original dimensions, but become of a much greater thickness, which may reduce their thickness until they burst.

An important point to be regarded in laying any system of pipes for the passage of water is to keep the waterway as uniform as possible; contractions and enlargements being very objectionable, as affecting the velocity of the current. On this account all such cocks as may occur in the course of a pipe should have a waterway equal to that of the pipe itself, a matter which is not unfrequently disregarded, on account of the expense of large cocks. On the first admission of water to a pipe which has a tortuous course, the passage is sometimes impeded by the lodgment of air in the upper bends of the pipe; to remove which, in the case of leaden pipes, plumbers resort to a very simple expedient. This consists in driving a nail into the pipe at or a little beyond the highest part of the bend; and, while it remains in, hammering up the lead round about it in the form of a little button or point. The nail is then withdrawn, and the pressure of the water causes the air to rush out violently. When it has all escaped, and water begins to follow it, the hole is closed by a few strokes of the hammer upon the portion of lead beat up about the nail. If the pipe be so situated that air cannot enter at either end, it will, after this treatment, continue to yield a full supply for years. In the pipes connected with waterworks, however, many cases occur in which air has frequent access to the pipes, and then an apparatus must be used which will allow the air to escape wherever the pipe is being charged with water. An air-pipe with a cock to open and close by hand would be troublesome; but in some situations an open air-pipe may be used, rising to a higher level than the mouth of the pipe, in which case the water will rise in the air-pipe to the level of the reservoir from which the pipe is charged, but will not overflow, and the air will rise in bubbles through it. Desaguliers contrived an apparatus for removing air from such bleedings, in which, after the escape of the air, the water was supplied by a kind of ball-cock acted upon by water escaping from the pipe into a small cistern adjoining it; and Robison describes a very simple contrivance for the same purpose by the late Professor Russell, of Edinburgh, of which Fig. 4 is a sectional representation. In this a cylindrical chamber is screwed on to an opening in the pipe, and a small aperture in the top of the chamber serves for the escape of the air, while a cylindrical copper float placed in the chamber, with a quantity of soft leather attached to its upper extremity, rises as to close the aperture as soon as water enters the chamber. Whenever the pressure of the water in the pipe is considerable, such an apparatus should be fixed a little beyond the highest part of the bending, as the water will force the air forward in the pipe; and to insure the removal of all the air, it is sometimes necessary to make the air-box or pipe communicate with the main at more than one point.

In addition to the authorities quoted in the body of this article, some information has been derived from Barlow's Treatise on Machinery and Manufactures, forming part of the Encyclopaedia Metropolitana; from Ree's Cyclopaedia, articles 'Pipes' and 'Water'; and from Robison's treatise on Waterworks, in the Encyclopaedia Britannica.

As an appropriate appendix to an article on Waterworks, we here present, from the latest complete returns published by parliament, a tabular view of the operations of the several companies by which the metropolis is supplied with water, about the year 1834. As will be seen by the notices of some of the more prominent improvements in the body of this article, very much has been done since that time to improve the supply, and at very great expense; but the cost of water to the consumers has not
generally been raised, the companies looking for their re-
muneration to an increased and constantly increasing ex-
tent of custom. These returns show the quantity of water
supplied by the eight companies named to have been
about 235,914,761 hodgesheads annually; this enormous
quantity being distributed among 191,066 houses, factories,
and other buildings; the individual supplies to each vary-
ing from 100 to 350 gallons daily.

Table showing the Number of Houses, Quantity of Water, &c., supplied, by the Metropolitan Water Companies, according to Returns made to Parliament in 1834.

WATERFALLS. In the article VALLEYS we have
arranged a general view of the main features of the earth's
surface, and a series of inferences touching the forces
whereby the diversified forms of hills and valleys have been
formed. It is natural to suppose that these features, on the
scale they appear permanent, because the great modifying
agents which produced them have passed away, are
really undergoing continual change from causes in daily
operation, and the most gradual one is that adopted by the
water. But incessant water, flowing down the river,
and reaching it by the depression of the land, is the
primary cause of decomposition by the
atmosphere. Rain washes away the diacreation
occasioned by varying temperature and chemical processes;
the hills lose and the valleys gain, and the balance of
decay and renewal of land is thus adjusted only to salt and
the sea in the basin of the sea. Among the pheno-
mena which show this mutability of the supposed
solid land with most distinctness, are interruptions to the general
uniformity of the inclinations of valleys and the even slopes of
hills, and these changes of character points of variation of the intensity of the agencies excited by the slope.
These interruptions of uniformity are all referrible to the unequal
power of resistance which rocks of different hardness, or
dissimilar position, or unequal thickness, or unlike modes of
association present to external agencies. Thus have been formed round the high limestone hills of the northern
counties a series of rocky terraces, not less regular than
the escarpments made by military art; and thus the oolitic
ramparts, and show how tremendous in masses of sand and clays of the broad plains of the clays of the red marls which margin the Severn and the Avon. On
these grand features of the earth's surface the action of the
atmosphere (including chemical and mechanical opera-
tions in its various agencies) is successively exerted; but when the
spread out, as on the slopes of hills, in the limestone dales of the northern counties of England, the waterfalls are daily receding up the
streams, and thus are the falls of Niagara forced con-
tinually further up the river. The process is by no means
certain. Beneath Hardrow Force, in Yorkshire (a fall of 59
feet), the effect since the general valley of the Yore was
occupied by a stream is marked on the north side of the
river by the remarkable line of cliffs above known as the
Avon. But wherever we look the great agencies of
erosion, of the surface of the earth, are continually
acting upon the rocks with power and precision.

WATERFORD, a maritime county in the province of Munster, in Ireland, bounded on the south by St. George's Channel; on the east by the estuary called Waterford harbour, which separates it from Wexford, and by Kilkenny; on the north by Tipperary; and on the west by Cork. Its
length, from east to west, is 52 miles; and its greatest breadth, from the estuary, is 15 miles. It is
watered by the River Suir, by the River Barrow into which of Youghall town, to the county of Clonmel, is 29 miles.
The area of the county, exclusive of the county of the city of Waterford, is 395,630 acres, or 1244 square miles, which
is about equal to the territory of Connemara, and about one-
half of the whole of Ireland. The population, in 1811, was 149,335,
being 318 to a square geographical mile, which is higher than the mean density of Ireland, but much below that of
several counties in each of the four provinces. The number
of houses, in 1831, was 24,840, inhabited by 30,191 families,
and by above seven persons to each house. The number of
persons to each family was 5.8, and dividing the area of
the county by the number of families there would be 15-6

Not including any allowances for necessary works and improvements, as
expenditures of filtration, &c.,

Under 132 gallons per house per day for street washing.
acres to each. Waterford city is 84 miles in a direct line from Dublin, or 93 miles by the road through Carrlow, Castledermot, Ballymore, Kilcullen, Naas, and Rathcoole; in 82° 16' N. lat. and 7° 7' W. long. Hook Tower (light-house) at the entrance to Waterford harbour is in 52° 25' N. lat. and 6° 55' 56" W. long. The county itself lies between 51° 56' and 52° 29' N. lat. and 6° 58' and 8° 9' W. long.

Coast-line.—From Blackball Head, near the entrance of Youghall Harbour, the eastern and northern boundary of Waterford, the general direction of the coast is east for three or four miles, where it trends to the north-east to Helvick Head, the western head of Dungarvan harbour. This harbour does not afford very good anchorage. From the entrance to the coast of Tramore Bay, which has a level beach three miles in extent. The coast is flat, and very dangerous to shipping, as the tide sets in with great force, and with the south-west winds there is a heavy sea. There are bascins on the eastern and western boundaries of Tramore and Dungarvan, a distance of twenty miles, the whole coast is rocky, and often unsafe from the want of shelter. About five miles east is Red Point, the south-western extremity of Waterford harbour; and a mile farther, within the harbour, and a mile from the sea, the port of Dunmore, which has a pier and breakwater, and is the post-office packet station. The width of Waterford harbour is here about two miles. There is a lighthouse on Hook Head, at the entrance of the harbour on the eastern side. There are some remarkable caverns on the coast.

Surface and Geology.—The general character of the county is mountainous. The great mountain-tract which extends from Waterford on the east coast to Dingle Bay, and is bounded on the west, and the south by the parish of Waterford: it is interrupted on a line from Dungarvan to the valley of the Suir, west of Clonmel, by the southern extremity of the great plain which occupies the central part of the county. These mountains occupy the part of the county west of Dungarvan, are among the highest and wildest in Ireland: the height of Monavallogh is 2538 feet above the sea. There are four small lakes in the Cummeragh Mountains, two called Comma Loughs, and two called Youghall Lough; but the sons of the county is only five or six acres: they contain several kinds of trout, and in one eel are found. The Waterford mountains contain two varieties of slate: first, the old transition slate, coloured grey, which is quarried at Glenpatrick, and is much in request for building, and for roofing. The second was a newer slate rests on the older; the lower portions of its strata consist of alternating beds of brownish-red quartz conglomerate and coarse red slate. These strata are succeeded by alternations of red and grey quartz rock, red quartz slate, and grey slate; which beds accumulate and recede farther from the conglomerate, till at length the upper beds produce varieties of purple, brownish-red, and reddish-grey clay-slate, which are known as roofing-slate, particularly in the valley of the river Blackwater near Lismore. These strata undergo successive undulations, the ridges of which have an east and west direction, and the beds almost incline towards the valleys of the principal rivers, and thus form troughs, which are filled by indurated sandstone and secondary limestone, whose strata rest conformably on the clay-slate. The new slate series contains abundance of marine and even vegetable organic remains. The limestone in the counties contains all the fossils of the carboniferous period. The work is to make the alternate beds accumulate with the lower beds of the limestone, also contains fossils similar to those found in the limestone. The subjacent sandstone frequently contains coal-marks, and other vegetable remains, resembling those which occur in the Coal Measures. The strata are much reddened, for the are at times red, and in the intervals of undu- Like the slate district contains several copper and lead mines, some of which, as at Knockmahon, are worked: valuable non-ore is found at Minehead and Ardmore, and at the latter place copper and lead also. Chalybeate and vitric springs exist in several parts of the county.

Hydrography and Communications.—The Suir, which rises in the north-east of Tipperary, after being joined by the Nier, from the Cummeragh Mountains, forms the boundary-line between Waterford and Tipperary and Kil- kenny. The united waters of the Suir and Barrow form the estuary called Waterford Harbour. The Suir is navigable for large vessels up to Waterford city, and to Carrick-on-Suir for those of which the draught does not exceed seven feet. The Barrys, the channel by which the produce of Tipperary, Kilkenny, and the western portion of Waterford are exported. The Blackwater, which rises in the Kerry mountains, enters the county on the west, and runs due east to Cappoquin, where it turns southward, and forms a part of the eastern boundary of Youghall Harbour; after receiving midway the river Bride. The Blackwater produces vessels of a hundred tons to its confluence with the Bride, and for vessels of seventy tons as far as Cappoquin. The Bride, a sluggish stream, is affected by the tide for a short distance, and is navigable for small craft. From Cappoquin to Lismore there is a three miles long, made at the expense of the duke of Devonshire. The Leckey, Brecy, Colleigh, Mahon, Phinsk, Clodagh, and some others, none of them of importance, except for drainage, fall into the sea at various points of the southern coast.

The mail-coach road from Dublin to Waterford, 75 miles, enters the county within two or three miles of Waterford city. The mail-coach road from Waterford to Cork, 87 miles, passes through the county. The, Cappoquin, Lismore, and Tallow, between which place and Yougall it leaves the county, but again touches Waterford before it finally leaves the county a short distance before reaching Youghall. The other roads are—Dungarvan to Newmarket, seven miles; Dungarvan to Youghall, through Pilltown, both over the mountains; one from Cappoquin to the mountains; one from Waterford to Tramore. The above are the roads of importance. There are several places north-north-east or north-west of Waterford left the coast of Waterford, except the Limerick mail-coach road, which runs within the county to Carrick-on-Suir on the Waterford bank of the river, and from Carrick to Clonmel on the Tipperary side.

Agriculture and Condition of the People.—It is estimated that 353,000 acres are cultivated, and 118,000,000.

The estimated rental for the county averages about 12s. 6d., including extensive districts which scarcely produce anything, except for drainage, and are altogether unproductive. Waterford is the principal dairy county in Ireland. A large part of the best land is occupied in dairy-farms, and the Waterford butter bears a high character. When Arthur Young visited Ireland sixty years ago, not one farm was enclosed. The produce of the county is now much larger. The Appendix P. to the Irish Poor-Law Inquiry, contains the result of inquiries both into the state of agriculture and the condition of the people in the baronies of Decies-without-Drum and Mid- dleham; and the following information is chiefly derived from this source.

The barony of Decies-without-Drum contains a large mountainous district, with a great breadth of low uniform ground extending from the flood of the river Blackwater to the flood of the river Barrow, a distance of about seven miles. The thin soil on the mountains affords a very moderate pasture to sheep and store cattle; but descending to the more level land, where the soil is deeper and better, attempts are made to bring it into cultivation; and though some wheat is grown, yet, from its elevated situation, oats are the most suitable crop. The fences on these reclaimed lands are very imperfect, and cattle and sheep cannot be kept out of the corn-fields without herding. There are facilities for the erection of dry stone walls, but the general practice is to make the fences of these land, in the Report of the Railway Commissioners.)

The clay-slate district contains several copper and lead mines, some of which, as at Knockmahon, are worked: valuable non-ore is found at Minehead and Ardmore, and at the latter place copper and lead also. Chalybeate and vitric springs exist in several parts of the county.

The clay-slate district contains several copper and lead mines, some of which, as at Knockmahon, are worked: valuable non-ore is found at Minehead and Ardmore, and at the latter place copper and lead also. Chalybeate and vitric springs exist in several parts of the county.
spring food. The sheep are a cross of the Leicester; the pigs of an improved kind; but the greatest attention has been paid to the breed of horses, which are superior in most points to those in other parts of the south of Ireland, and very active strong animals may frequently be seen in the common country carts. A better description of agricultural implements has been introduced within the last few years, such as iron Scotch ploughs and double harrows. A great many farmers use rollers, but winnowing-machines are only used by the largest landholders, the corn being commonly winnowed by women in the open air: the old single heavy harrow is still used by the majority of farmers. The greater part of the barley is held under lease, the tenant depending upon lives, and running from twenty to fifty years before they fall in: the farms are rather above an average size for the south of Ireland. In all recent leases clauses of non-alienation and non-subletting have been introduced. Rent is paid either in the form of a tithe of butter and pork than, or in England, on cash. There is a large field for the profitable employment of labour in road-making, draining land, improving fences. The statement of the farmers in the barony is that they employ one man to every thirty or forty acres under the plough; a much smaller proportion of land than in England gives employment to one man; but this labour costs only 1s. 5d. in Ireland, and between 3l. and 4l. in England.

In the barony of Middlethird, which the assistant commissioner said, it is stated that an experiment is about to be tried, whether it would be more profitable for the dairy farmers to make cheese instead of butter. Conacre, in the barony of Decies-without-Drum, is called "dairy-ground;" the farmer ploughs and manures the land, which is let to an acre, and the labourer and his family do all the other work; the rent, either money or labour, being paid before the crop is allowed to be taken from the ground. There is often a difficulty in getting regular labourers, unless potato-ground is given to them. The usual rotation of crops in the barony of Middlethird is potatoes, wheat, potatoes, oats, and grass-seeds; but the smaller farmers often take two corn-crops together. Out of 2,049 acres, 20 acres were under tillage, including 227 under five acres, and only 101 exceeded 50 acres.

The general state of the peasantry is said to be very curious, ranging from the height of sixty feet.

CLOMNEAL.

Dungarvan is a post-town, 23 miles west-south-west from Waterford, situated in the bay or haven of Dungarvan, on the estuary of the river Colligan, which is crossed by a fine bridge of one arch, built entirely at the expense of the Duke of Devonshure. Part of the town is north and west of this river, and parts of it, especially the market-place, is called the Abbey Side, from an abbey which was formerly there. Dungarvan is an old seaport, and was incorporated in 1463. Within the walls of a castle, built by King John, and now in ruins, the barracks are established. The sciences are for the most part narrow and dirty, but there is a handsome church, a Roman Catholic chapel, and a good market-house. There are two banks, the National Bank and the Provincial Bank. The population, in 1821, was 5105; in 1831, 6217. The inhabitants are chiefly employed in fishing. It is a good deal frequented in summer as a bathing-place. In the year 1833 the exports from the port of Dungarvan were—corn, 97,224 cwt.; provisions, 13,150 cwt.; copper-ore, 28,800 cwt.; all of the value of which was 69,086l., which, with other articles, estimated at 400l., gave a total estimated value of 69,486l. In the same year (1833) the imports were—coals, 357,216 tons; iron, 290 tons; oak-bark or tannin, 129 tons; hemp, 2704. Out of 2219 acres of land, 9877 acres were used for agriculture; 6010 bushes; glass and earthenware, 20 packages; the estimated value of which was 11,012l., and with other articles estimated at 5300l., gave a total estimated value of 16,312l. The amount of the excise duty on malt was 540l.

The town is 24 miles west of Dungarvan, 17 miles south of Waterford, and 24 miles north of Lismore. It was 235l. in 1831; the estimated value of which was 98,514l., which, with other articles, estimated at 400l., gave a total estimated value of 101,986l. It was inhabited by fishermen and pilots, five or six miles below Waterford, and about the same distance from the mouth of the river.

Portlaw, a neat little post-town to Waterford, is a landing on the west bank of the Suir, or rather of Waterford Haven, opposite which is a safe roadstead where hundreds of vessels of large burthen may anchor in safety. The village, which consists of two streets, is near the town of Waterford, and about six miles below Waterford, and about the same distance from the estuary of the river.

Mayfield, a village in the neighbourhood of Waterford, has an extensive cotton manufacture, which employs about 1000 persons. The calico market is not only in the town, but to some extent in England.

Passage, distinguished as East Passage, is a defensive post on the west bank of the Suir, or rather of Waterford Haven, opposite which is a safe roadstead where hundreds of vessels of large burthen may anchor in safety. The village, which consists of two streets, is near the town of Waterford, and about six miles below Waterford, and about the same distance from the mouth of the river.

Lismore, a small but neat and regularly-built town on the river of Lismore, about nine miles south from Waterford, is much more esteemed in this part of the county than any other place; it is said to be a bathing-place, the beach being very firm and convenient for the purpose. The bay is very dangerous for shipping; it is sometimes mistaken for the bay of Waterford, and shipwreck by the occasion. The town has a church, a chapel, a market-house, and an assembly-room.

Tramore, a small but neat and regularly-built town on the south side of the river Tramore, about nine miles south from Waterford, is much more esteemed to be a bathing-place, the beach being very firm and convenient for the purpose. The town is a fishing village, and the number of fishermen now returned is two for the county and one for Dungarvan.

The county is in the dioecese of Waterford, which is a joint see; the dioceses of Cashel, Emily, Lismore, and Waterford are in the same; the population in 1831 was 28,719, or one in 270 persons. The average number of committals for criminal offences is
under 300, two-thirds of which are chiefly for assaults, riots, and attempts to retreat, and similar offences. In 1836 the grand jury recommended that the assizes and sessions should be held at Dungarvan instead of Waterford. The county gaol at Waterford is one of the best managed in Ireland. The county lunatic asylum is at Waterford. There is no county infirmary. There are fever-hospitals at Waterford, Dungarvan, Lismore, and Tallow; and dispensaries at Cappoquin, Clasheen, Dunmore, Kilmeathomas, Killbarrymeaden, Tramore, Dungarvan, Tallow, Lismore, Ballyduff, Bonmahon, and Drumcannon, supported chiefly by grand-jury presentsments. In 1838 the number of patients relieved by the fever-hospitals and dispensaries was 19,231, of whom 15,739 attended at the different institutions, and 4,062 were attended at their own dwellings. The number of admissions into the fever-hospitals was 775, or 1 in 191 of the total population of the county. On the 1st of January, 1840, the number of patients in the lunatic asylum was 101, but the institution was only calculated for 60.

The following Poor-Law unions have been formed in the county:

In 1840 there were fifty six schools under the National Board of Education, containing 5807 scholars—3227 boys and 2540 girls: the number of male teachers was 32, and female teachers 19.

The county constabulary (exclusive of the city) consisted, on the 1st of January, 1843, of 1 county inspector of the second class, 4 sub-inspectors of the first class, and 2 of the third; 1 head constable, first class; and 6 of the second class; 47 constables, 191 sub-constables, first class, and 28 sub-constables, second class. The expense of this force for 1842 was 8383£. The amount of grand-jury presentsments for the year 1839 was as follows:

- New roads, bridges, &c. | £4,456
- Repairs of ditches | £6,669
- Court and sessions-house, repairs, &c. | £49
- Other expenses | £968
- Constabulary and payments to witnesses | £2,065
- County officers not included in the above | £2,446
- Public charities | £2,846
- Compensation of government advances | £5,113
- Miscellaneous | £3,246

£29,094

The grand-jury presentsments for the county of the city of Waterford were £39,821.

The manufacturing industry of the county is insignificant. At Waterford there are some large establishments.

Waterford, City.] A few years ago a cotton factory, for spinning and weaving, was established at Mayfield, in which about nine hundred persons were employed. The fisheries might be profitably extended, but the unprotected nature of a great part of the coast is said to discourage this pursuit. In 1836 they employed 101 half-decked vessels, of 1688 tons, employing 565 men; 32 open sail-boats, and 550 row-boats, and 1250 men; making altogether 2156 persons.

History and Antiquities.—Dr. Smith, who in 1745 published an account of 'The Antient and Present State of the County and City of Waterford,' states, on the authority of Plutarch, that the Menapii, a Belgic colony, were the antient inhabitants of Waterford and the adjoining county of Wexford. The Desii, from the county of Meath, were a powerful clan at the period of the English invasion, when their importance was nearly destroyed. In 1717 Henry II. granted the city of Waterford and the adjacent province to Richard Le Poer, his marshal, and by marriage the estates and honours of his descendants came to the Beresford family, who still retain large possessions in the county. The county suffered little during the rebellion in 1798. The city of Waterford was the chief scene of most of the historical events of importance.

Many remains of antiquity are found in the county. At Ardmore is one of the round towers, and there are found in several parts of the county interments, earthworks, P. C., No. 1896.

barrows, and cromlechs. A large double trench, called by the Irish 'the trench of St. Patrick's cow,' may be traced for seventeen or eighteen miles across the Blackwater towards Ardmore; it corresponds with the work called the 'King's Cast;' in the time of Armagh and Down. A second trench runs westward from Capel Curig, in Mountains of Cor. At one period there were twenty-four religious establishments existing in the county, and the ruins of some of them still remain, as at Mothill, Dungarvan, Stradbally, and Lismore. The ancient castles and fortified places were also numerous.

(Smith's History of Waterford; M'Culloch's Statistics of the British Empire; Parliamentary Papers on Ireland.)

WATERFORD, the capital of the county of Waterford, is situated on the river Suir, in the 52° 10' N. lat. and 7° 5' W. long. It is a county of a city, and includes in the boundary of the county 9478 acres on both sides of the Suir. The city itself is entirely on the south bank of the river, and is about a mile long. A noble quay extends for a whole mile through the town, from which the city rises gradually. The situation is very fine, but the greater part of the streets are dark, dirty, and mean-looking. Waterford is about 12 miles from the sea, and vessels of 500 tons burden can lie by the side of the quay, but larger vessels anchor about six miles westward of the quay, opposite the village of Passage. The river is crossed at the upper end of the city by a very long wooden bridge, which opens in one part to allow vessels to pass. The bridge was designed by Lemuel Cox, an American, and was built about 1723. The estuary of the river is nearly of a mile wide; the opposite banks are very beautiful, rising gently with green wooded hills.

The town and suburbs occupy about 883 acres. In the county of the city there are twelve parishes, three of which are entirely agricultural, and nine partly agricultural, and partly occupied by the town and suburbs. In December, 1831, the total number of houses in the county of the city was 3719, of which 3376 were in the city and suburbs, and of these latter 1003 were thatched. The number of houses, of 20. rent and upwards, was 1671. The population of the county of the city, in 1821, was 28,679; in 1831 it was 28,921. The population of the city and suburbs, in 1831, was 26,577, the county part of the population being 2441. Upwards of 25,000 were Roman Catholics.

Waterford has been an improving town for many years, but it will be seen that the increase in population has been very small. It has probably been kept down by emigration. Few very new houses are built. In the worst parts of the town the houses are anything but neat; five or six families are sometimes found living together in a hovel, entirely without furniture, and with nothing but straw to lie upon.

The principal public buildings are—the cathedral, an elegant modern structure of brick, which is of hewn stone, with a double front, and commands an extensive view across the river into the county of Wexford. There are three parish churches, four Roman Catholic chapels, and places of worship for the Quakers and other sects. The other public buildings are—of tourist, from an exchange, a custom-house, a theatre, an assembly-room, barracks, and a gaol. Among the charitable institutions are a house of industry and an hospital for the poor.

Waterford, before the Reform Act, returned one member to parliament. It has returned two members ever since the Reform Act of 1832. The present number of electors is 900 freeholders and 900 freeholders.

The assessments in the town only were, in 1830—£2054. 8s. 7d.

cess, 720. - ministers' money, 248L; lighting cess, 770L; the total amount raised by these assessments being £158L, from about 1800 ratepayers. The grand-jury cess 'evicted' on the county of the city, in 1830, was 434l. 14s. 10d., but the amount of this assessment varies considerably in different years.

The vicinity of Waterford is chiefly with England, and consists for the most part of agricultural produce, butter, pork, &c., and, since the introduction of steam-vessels, of live-stock. The exports from Waterford, in 1835, were corn, meal, and flour, 1,933,854 cwt.; potatoes, 20,048 cwt.; sugar, 165 cwt.; copper-ore, 48,000 cwt.; teathers, 1040 cwt.; wine, 5,402 gallons; beer, 170,000 gallons; cotton manufactures, 180,200 yards; calk-skins, 6400; cow and oxen, 4410 head; horses, 242 head; sheep, 3536 head; swine, 7438; mutton, 7638. Pig-killing, which, added to other articles estimated at 77,700L., gave an estimated value of 1,821,245L.

The imports for the same year (1835) consisted of a great variety of articles required for purposes of trade and general consumption, the total estimated value of which was 1,274,154L.

According to a Return to the House of Commons, dated March, 1842, the number of vessels above 50 tons burden, registered at Waterford, was 115, the total burden of which vessels was 31,400 tons. The number of vessels registered at the town for the year 1841, was 183,510L. 15s. 3d.; the net receipt for the previous year was 161,752L. 5s. 5d. There was a packet station at Waterford for conveyance between Waterford and Milford daily; the number of packets is five, which are kept up at an average expenditure of about 14,000L. a year, the amount received from passengers being about 1700L. a year.

In 1835 there were seven steam-engines in Waterford, equal to ninety-horse power, for manufacturing purposes. In 1836 there were 339 cotton power-looms.

The amount of excise duty on malt, collected in Waterford in 1836, was 9840L. 3s. 6d., for 76,182 bushes of malt.

The annual income of the Provincial Bank in Ireland, and the Branch Bank of Ireland. There is also a savings-bank, in which the number of depositors on the 20th Nov., 1842, was 3469. The expense of management for the year 1841-2 was 270L., including 242L. salaries. The smallest sum on which interest is allowed is 15L. In some English savings-banks interest is allowed on 2s. 6d.

The newspapers are—the Waterford Weekly Chronicle, the Waterford News-Letter, weekly; the Waterford Mirror, three times a week; and the Waterford Mail, twice a week.

In 1840 an act was passed for a railway between Limerick and Carrick-on-Suir, passing through Waterford; but the act was not carried into effect, and has expired.

Waterford was originally founded by the Danes about A.D. 850, and it was their chief possession in Ireland for some centuries. In 1170 it was taken by assault by Strongbow, one of Pembroke; and in the following year Henry II., when he passed to take possession of Ireland, then newly conquered, landed near Waterford, and paid a visit to the town, which was afterwards restored and enlarged by Strongbow. Waterford received its first charter from King John, who resided there for some time; and when, in 1214, on account of its distance to the English, gave it several other charters and privileges, especially Henry VII., for its opposition to Simbel and Perkin Warbeck. All its charters however were seized and annulled by James I., on the ground of the nonconformity of the chief magistrates, and Waterford remained without a charter from 1617 to 1629, when a new and more extensive one was granted by Charles I., which is the one now in force. The immunities granted by this charter were very great, and included, among others, an exemption from the payment of duties of poundage. Waterford was unsuccessfully taken by Irish Carthaginians, and included, among others, an exemption from the payment of duties of poundage. Waterford was subsequently besieged by Cromwell, but

WATERING, in Horticulture, the process of applying water artificially to plants. Water in a greater or less quantity is necessary to the existence of the whole vegetable kingdom: not only do the elements of water enter into the composition of the tissues of plants, but by its agency the various saline ingredients, as well as certain gases that enter into the composition of vegetable tissues, are carried into the plant. Water also exerts an influence on the temperature of the soil and of the plants to which it is applied. It is on these accounts that the application of water to plants is an important process in horticulture, more especially when carried on in the open air. Plants require little moisture, as the processes of life are at that period very inductive, but at the same time a small quantity is required in order to meet the demands of approaching activity. If plants are supplied with too much moisture, the whole plant is enfeebled. The largest supply of water is required when plants are growing rapidly and at the season when they are putting forth their leaves. When plants have ceased to grow, or when the leaves and flowers are falling, the water required by the plant is very much reduced; for, however the object in the culture of plants is to render either their leaves or fruits as succulent as possible, they should be supplied with abundance of water. This is done with spinach, lettuce, and other oleraceous plants, and by this means their leaves are rendered more tender, the plants are grown more quickly, and those parts of the plants, which are often disagreeable, are dulled. The same thing is done in the cultivation of the strawberry, where the object is to render the fruit as large as possible. In this case however the large size of the fruit is always obtained at the expense of its flavour. Even plants bearing succulent fruits, as the melon, &c., may be over-watered, and the flavour of their fruit quite destroyed. In supplying water to all plants due regard should be had to temperature, as, for example, plants which require much water in cold weather, require less in hot weather. Watering in the open air is not often more productive of disadvantage than of real service to plants. When plants are watered naturally, the whole air is saturated with humidity at the same time as the ground; this is not the case when water is supplied under artificial agencies, as by means of the water added, the air is not so strongly charged with moisture, and the plants do not grow as fast as when watered artificially. This operation is usually performed at dry weather, and must necessarily be very limited in its effects; it can have little if any influence upon the atmosphere: then the parched air robs the leaves rapidly of their moisture, so long as the latter is abundant; the roots are suddenly and violently excited, and after a short time the exciting cause is suddenly withdrawn, by the momentary supply of water being cut off by evaporation, and by filtration through bibulous substances of which the soil usually consists. Then again, the plant is not supplied with water, and is excited to the effect of lowering the temperature of the earth, and such a lowering does not take place when plants are refreshed by showers, because at that time the dampness of the air prevents evaporation from the soil just as it prevents perspiration from the body. Much evaporation of water upon the surface has, after a little while, the effect of 'puddling' the ground and rendering it impervious, so that the descent of water to the roots is impeded, whether it is communicated artificially or by the fall of rain. It is therefore doubtful whether artificial watering in the open air is advantageous unless in particular cases; and most assuredly, if it is done at all, ought to be much more copious than is usual. At the same time the practice is at present very general, and there are some advantages in it, independent of supplying plants with water, which is frequently very effectual for removing insects from the leaves of plants, and also for removing dust and dirt in

Inglis's Journey Throughout Ireland, 1834; Barron's Tour Round Ireland, 1835; Report on the Parliamentary Representation of Ireland, printed June 8, 1832; Second Report of Commissioners on Railways in Ireland, 1838; various Parliamentary Documents.)
exposed situations. Mildew is also prevented in annuals by abundant watering. The fungi which produce or are found on mildewed peas, and those which destroy the stalk and onion, may be removed by abundant watering. Where the leaves of plants are injured, this should never be done whilst the sun is shining upon them, as this increases the evaporation, the evils of which have been already spoken of. The morning and evening are the best times for watering these plants. If, in the middle of the day, the roots alone should be watered. After transplanting, whether of young or old plants, in pots or in the open ground, the watering of the plant is always recommended.

In those several instruments are made use of as the engine, the syringe, and the watering-pot. These are made either to throw water through tubes of various sizes so as to apply the water to a particular point, or by means of a rose which is appended to the tube to distribute the water over the plants. Where the water is applied to the roots of the plant are to be watered, and the latter when it is wished to wet the whole surface. Where a stream can be made use of, an effectual way of watering plants is to have a sluice by which the water of the stream may be let on and off as may be the case, the sluices are usually made of a paper.

This is the best mode of watering water-cresses and other plants requiring abundant moisture. Where there are water-stocks, pipes are sometimes laid for supplying compartments of a garden. Lawns and plots of grass may be watered in the same way.

WATERING OF LAND. [IRRIGATION.]

WATERLAND, DANIEL D.D., an eminent English theologian, was the son of the Rev. Henry Waterland, rector of Wesely or Walsley, in Lincolnshire, where he was born in 1705. After his education at the free school of Lincoln, he was admitted to Magdalen College, Cambridge, in March, 1699, obtained a scholarship in December, 1702, and was elected a fellow in February, 1704. Continuing to reside at the university, and to act for his father in his pastoral charge, 'he resided at Cambridge until the 3rd year of his above 21st year, when he was admitted to the degree of A.B. and continued his studies at the university, and obtained a degree of B.D., in which he was sometimes honored at Oxford.

Dr. Waterland appears to have first come forth as a controversialist in 1718, in an answer to Dr. Whitby's last examination on Bishop Bull's 'Defence of the Creed,' and 'An Answer to Dr. Whitby's Reply' to that attack. In 1719 he handled the same subject with more elaboration and effect in 'A Vindication of Christ's Divinity, on which occasion he greatly distinguished himself, by the defence of his theory, the rights of the Church, and the subject of his first book 'In Answer to a Young Student,' under the name of a degree of D.D., in which he was sometimes honored at Oxford.

WAT (132)

(Houbraken, Schouburg der Nederlandsche Konstchil- ders, &c.; Bartsch, Peintre Graveur; Huber, Manuel des Artistes, &c.)

The Thames, one who rows a boat on a river for the conveyance of passengers. The only large body of watermen in England are those employed on the river Thames at London. Before the introduction of coaches they were a very essential class for the conveyance of persons not only between London and Westminster, but London and Gravesend, and up and down the river to the various places on each side. The Thames was then the great highway. Stairs and watergates were numerous on the north bank from London to Westminster, where the many palace gates of the court having its landing-place, its barges and wherries, and its private retinue of watermen, or bargemen, as they were then commonly called. Processions on the river, water-tournaments, boat-races, and other aquatine amusements were frequent, near London, and the fare for a passenger, with his truss or farthell, from London to Gravesend or Milton, was 2d. Stow computes that there were as many as 2000 boats in his time, that there were 40,000 watermen on the rolls of the Watermen's Company, and that in 1796, according to 100 men for the fleet. Doubt he included in this large number the private watermen of the court and the nobility. John Taylor, the 'water-poet,' as he styled himself, complains bitterly of the increase of watermen: 'I don't think the new against augmenting the number of persons of worth or quality, but only against the caterpillar swarm of hirelings. They have undone my poor trade whereof I am a member.' Since that time the increase in the number of bridges and the introduction of steam-boats have still more reduced the number of watermen.

An apprenticeship of seven years on the Thames constitutes a free waterman. The watermen and lightermen are an incorporated company, founded in 1585, and dependent on the corporation of the city of London. They are regulated partly by their own by-laws and partly by the 7 & 8 Geo. IV., c. 75. The monopoly of labour held by this company is very extensive, embracing the whole of the river navigation from Staines to Yantlet Creek, with the exception of certain flat-bottomed ferry-boats and barges above Kingston, no person can ply in a boat for hire on the Thames who is not a member of the Watermen's Company.

The number of free watermen is between 4000 and 5000. In 1796, according to the Report of the Dock Committee, the number of free watermen was 8283. The number of boats licensed to carry passengers was 2728 on January 1, 1836. (Appendix to Report on the Port of London, p. 233.) The Trinity House Corporation share to some extent in the monopoly of navigation of Yantlet Creek, having the power to license certain king's seamen, besides pilots, to ply on the river; but the licences granted by them are under 200.

The act 7 & 8 Geo. IV., c. 75, for 'the better regulation of watermen and lightermen on the river Thames between Yantlet Creek and Windsor,' the court of aldermen are to fix the fares that may be taken for the conveyance of passengers; every waterman who shall demand and take for his fare more than is allowed, is to forfeit for every offence not exceeding 40s.; lists of fares are to be painted on boards and affixed at suitable plying-places; every waterman is to have a printed list of the fares in his boat, and if he shall refuse to produce the same, or not produce it, he shall be examined, and if the pawning be discharged from his fare, and the waterman shall pay for every offence not exceeding 5l.; the number of the boat and the name of the owner are to be painted on the boat; and a waterman wilfully avoiding a passenger, or having or using abusive language, is liable to a fine not exceeding 5l. Complaint may be made within thirty days after the offence to the lord-may or any justice within his jurisdiction. For other regulations less interesting to the public we refer to the act itself.

The Thames watermen have recently established a steam-boat company, in which any free waterman may be a sharer, but no other person.

A very handsome set of almshouses have been built on Penge Common, for 'poor, aged, decayed, and maimed free watermen and lightermen on the river Thames.' According to the statement made at the Anniversary meeting in June, 1843, forty-one houses had already been erected, the cost of which was 12,500l. of which 14,000l. had been raised by a debt of 1500l., towards which 1200l. was collected at the meeting.

(Knight's London, 'The Silent Highway;' Westminster Review, May, 1843; Act 7 & 8 Geo. IV., c. 75.)

The textile fabrics, whatever be their character, are pervious to water from two causes, viz., the existence of minute spaces between the individual fibres of the yarn, whether of silk, cotton, wool, or flax; and the rectangular meshes consequent on the twining of the threads. To close up these minute channels, as likewise the pores of leather, so as to impart a 'waterproof' quality to the material, has been the object of a large number of patents within the last twenty years, as likewise of recipes which have not been patented. Some of the former are large in number, others are subdivided, viz., 1, solutions into which the cloth is dipped; 2, varnishes applied to the surface; 3, interlayers of caoutchouc composition; 4, waterproof composition for leather.

1. In 1835 Mr. Hellewell, of Salford, took out a patent for a distillation, whereby the result was to render the leather, and other fabrics waterproof. According to this plan, for a quantity of woven material equal to 1000lb. weight, there are used 120lb. of rock alum, 80lb. of common whiting, and 300 gallons of water. This mixture is intended, by the chemical action of its ingredients, to yield a solution of alumine, with which the cloth is saturated. After the saturation, the cloth is passed quickly through a vessel containing a solution, at a temperature of 100° Fahr., of 40% white soap; water; the subsequent washing 9lb. of soap and 30 gallons of water to 50lb. of cloth. This laudable, according to the patentee's description, is for the purpose of fixing the alumine in the interstices of the cloth, and enabling it to resist the action of water. The cloth is finally washed, to free it from any impurities.

Mr. Hall, of Doncaster, patented in 1839 a method of waterproofing cloth by immersion. He describes two kinds of solution employed for this purpose: 1st, two ounces of pulverized alum are dissolved in a pint of distilled water; 2nd, one ounce of powdered alum in an ounce of half-pint of water, and another ounce of water; and the two solutions, together with two fluid dsnams of acetic acid, are mixed together, and allowed to settle. The supernatant liquor constitutes the required agent: 2nd, one ounce of dry white-lead is rubbed down in half a pint of water; one ounce of pounded alum is dissolved in another half-pint of water; and the two solutions, together with two fluid dsnams of acetic acid, are mixed together, and allowed to settle. When the cloth has been immersed in the supernatant liquor resulting from either of the above solutions, it is passed through a vessel containing the other agents, and is thus covered with a solution of boiled Irish moss, which acts as a mucilage.

There are other patents of a somewhat similar character to the above, and there have also been methods published which are not patented. Of these, one more example will suffice—the half an ounce of white-lead, or soft water till dissolved; dissolve one ounce of alum in two pounds of water; dissolve a quarter of an ounce of white soap in a pound of water; strain these solutions separately through linen, and then mix them together. Heat this to a boil, and fill it with another quarter of an ounce of white soap; then brush the cloth and paint it to the 'wrong' side of the cloth, on a flat table. When dry, the cloth is brushed, and then brushed again lightly with water. The intention of this process is to render the cloth impervious to water, but not to air.

2. The surface-application of varnish, as species of varnish has been the subject of many patents, which may be illustrated by two or three instances. About twenty years ago Messrs. Mills and Fairman introduced a composition, formed of glue, 40lb. of pig, and a small quantity of burnt umbel, which, when boiled over wooden frames, when the surface was thoroughly dried and the surface was similarly treated. This was not intended as a waterproof composition for ordinary clothing, but rather for tabletops, awnings, coach tops, boats, cloaks, and other coarse materials.

Mr. Newberry's patent, taken out in 1840, is for a mode
of applying water-proofing composition in such a way as to leave one side of the woven fabric free from its influence, thereby rendering the other side a texture nearly resembling that of ordinary cloth. The method consists in saturating the cloth with the waterproofing composition, and exposing one surface only, in such a way that the atmosphere, or artificial heat, may harden the composition on that surface into a good, impervious coating; while the other surface, being kept moist during the drying of the first, is cleansed from the composition by means of spirit of turpentine. Mr. Newberry describes three modes of effecting this object. In the first mode the cloth or woven fabric is stretched over a frame, and after being saturated with the composition, is allowed to float on a layer of oil till the upper surface is dry; after which the lower surface is cleansed from the composition. In the second mode the cloth is stretched double, or in two plies, over a frame, saturated with the composition, and then, when dry, the exterior surfaces, the contact-surfaces remaining moist until the time of removal. In the third mode recourse is had to a roller, on which the cloth is coiled, and a flat surface, stone, varnished wood, or other substance non-absorbent, to the composition. The table is covered with a layer of the composition, and the cloth, being uncoiled and laid down upon it, is pressed and rolled till every part becomes wet by the composition beneath. In this way the upper surface may be cleansed while the lower one is dried. The whole is then exposed to a drying process. Mr. Newberry's patent relates rather to the mode of proceeding than to the kind of composition employed.

3. The application of a layer of cement, gum, or varnish between two layers of substances, was deemed to render the inner one impervious to water, has been practiced under many different modifications, including that which is known by the name of the inventor, Macintosh. In the year 1824 Mr. Weise of Bermondsey devised a peculiar kind of waterproofing for cloth, which was patented under consideration. This fabric was to be used either as a material for hats and bonnets, in lieu of the usual felted beaver, or as a cloth for other garments. The materials consisted of beaver-fur, musk-fur, hare's wool, Spanish wool, flax, hemp, and the upper surface of the cloth was covered by a mixture of tallow, plant-resins and other materials, to render the fabric impervious to water. The patentee states that the cloth may be washed without fear, or at least not requiring the ordinary process of washing. It was used in Italy during the last century for making cloth. In 1830, Mr. Hancock, in the year 1830, besides describing a mode of applying a layer of caoutchouc-solution to the external surface of cloth, patented a peculiar kind of water-proof material. This consists of fibres of cotton, silk, flax, or hair, mixed up with caoutchouc. The fibres are cut to about an eighth of an inch in length, and then incorporated with the gum, in the proportion of an ounce of the former to 3 ounces of the latter; and colours, if required, may be given to the material by the addition of dry pigments. The mixture is poured out upon a cold tablet, and allowed to harden in form of an extended sheet; and this sheet, after being gently warmed, is rolled or impressed into the surface of the material. Of this material the patentee proposes that boats, shipping materials, boat-coverings, and numerous other articles may be formed; and the proportion of gum to fibre being regulated according to the purpose to which the resulting material is to be applied.

Among Mr. Sievier's ingenious applications of caoutchouc are two or three relating to waterproof cloth, patented in 1833. One method relates to non-elastic cloth. A woven fabric, of cotton, wool, or silk, is in the first instance coated with a solution of turpentine. It is next coated with a mixture composed of caoutchouc, spirits of turpentine, and litharge or some other drying ingredient. While yet wet, the cloth is covered with fibres of wool, cotton, silk, hair, or fur, cut into different sized pieces, and these are pressed into the cloth by rollers or brushes. When dry, the surface is brushed, and those fibres which remain unmoveable form a permanent surface to this double waterproof material. The inventor describes the appearance as being analogous to that of office or Hemp-fabric, according to the kind and number of fibres employed, and states that the cloth may be sheared if a short nap be required. Mr. Sievier proposes to produce multi-coloured patterns, by having blocks cut similar to those used by paper-stainers, floor-cloth-printers, and other manufacturers, by means of which one colour may be varnished ground-fabric by means of these blocks; a portion only will be thus covered, and the remainder is proposed to be covered with fibres of a different colour, applied as in the first method, but which will not adhere at the parts covered with the block-print. A mode is described of employing stencil-plates instead of the carved blocks.

Mr. Sievier's elastic waterproof material is thus formed:—thin sheets of caoutchouc are cemented by a solution of caoutchouc to gauze, bobbin-net, or other open material; and on this, as a ground, and with a similar cement of quick-drying caoutchouc, is laid a stratum of fibres. The fibres are pressed and dressed as in the former instance; but the result of the fabric differs in this, that the lower and external mesh of the gauze is both thin and give to the whole an elasticity which closely-woven textures cannot impart.

4. The attempts to render leather waterproof depend in general on the first attempts of the ancient Egyptians, who have already admitted the tannin, a substance imbibing being such as will repel or resist water. Many such methods have been proposed at different times, of which the mention of a few will here suffice. Melt over a slow fire a quart of boiled linseed oil, a pound of mutton suet, three quarters of a pound of yellow bees-wax, and half a pound of common resin, or smaller quantities in the like relative proportions; and with this mixture saturate the leather of new boots or shoes, while the latter is slightly heated. Another mode is to boil two pounds of bees-wax, two ounces of Burghley pitch, and two ounces of turpentine, in a pint of linseed oil, and with this mixture to saturate the leather; and another mode is to melt two ounces of resin, and half an ounce of white vitriol, to which add four ounces of spirits of turpentine and two ounces of white oak sawdust, and apply this mixture to the leather by means of a brush. 2. Apply a coating of tar to the leather; and after this is dried, apply a second mixture of one part of copalsia balsam with two of naphtha. Another mixture for this purpose consists of six ounces of caoutchouc boiled for two hours in two quarts of linseed or neats-foot oil. 3. Apply a mixture of one part of oil of turpentine to two parts of tallow and one part resin, with
which the leather may be completely saturated, the resin imparting an antiseptic quality to the tallow.

One of Mr. Sievier’s conivances is for rendering leather elastic and waterproof. A thin sheet of leather is cemented to a thin sheet of solid caoutchouc by a caoutchouc solution, and kept under pressure for five or six days. The compound fabric thus formed is nearly inelastic, because the leather has temporarily suspended the elastic power of the caoutchouc; but after the pressure is removed, of a hour’s duration, and that pressure cut to 180° Faris, the caoutchouc partly collapses, and the leather assumes a corrugated surface, similar to Morocco leather. The leather, rendered thus elastic and waterproof, is then manufactured into boots and other articles.

WATFORD [Hertfordshire.]

WATLINGTON [Oxfordshire.]

WATSON, Richard, D.D., was born in August, 1757, at Heversham, near Kendal, in Westmoreland; his father, John Watson, a man of no great property, who had been head master of the grammar-school from 1698: the family, supposed to have come originally from Scotland, had subsisted for at least three or four generations at Handendale, near Shap. His mother’s name was New. Old Watson had great reputation as a teacher; but Richard, who was the younger of his two sons, did not enjoy the advantage of having him for his master; for he had resigned his office in 1757, although he lived till November 1758. His son was a brilliant student, and his successor, who took little pains to give him an accurate grammatical training; and about a year after his father’s death he was sent, on an exhibition of 50l. belonging to the school, to Trinity College, Cambridge, where he was admitted a fellow-commoner November 1767. On his exhibition, to carry him through College, was a sum of 300l. which his father had left him; but he set bravely to work to make his way to independence by hard study and hard living. It is said that at first his dress was a coarse homespun garment of various colours. He offered himself as a candidate for a scholarship, which he obtained on the 2nd of May, 1775. In September following, while still only a junior soph, he began to take pupils, and continued to be so employed, first as an assistant, and afterwards as assistant, till 1776. By October, 1776, he became one of the head tutors of Trinity College. Meanwhile he had taken his degree of B.A. in January, 1759, when he was declared second wrangler (he says himself, he ought to have been first); had been elected a fellow of his college in October, 1783; had graduated M.A. at the commencement in 1792; and in November, 1764, had been, on the death of Dr. Hadley, unanimously elected by the senate to the professorship of chemistry. This was a very chuse position, for at that time Watson knew nothing of chemistry himself, but he did not disapprove the confidence that was felt, by himself and others, in his ardour, application, and quickness of comprehension. With the assistance of an operator, whom he had recommended to him, after immediately employing himself in his laboratory, he acquired such an acquaintance with his new subject as to enable him, in about fourteen months, to read his first course of lectures, which were honoured with a numerous attendance, and proved highly satisfactory. He afterwards delivered other courses, which were equally successful; in 1768 he printed a synopsis of the principles of the science under the title of Institutiones Metalurgicae; in 1769 he was elected a Fellow of the Royal Society, and during some years after this time corresponded with many chemists on philosophical Transactions. In 1771 he published An Essay on the subjects of Chemistry, and their General Divisions; in 1781 he published two vols. 12mo, of Chemical Essays; a third appeared in 1792; and a fourth in 1796 containing an account of an apparatus which has always been very popular. But Watson’s first publication, properly so called, was An Assize Sermon, preached at Cambridge, 4to, 1769. About two years after this, in October, 1771, he was unanimously elected to the distinguished office of regius professor of divinity, although he was at the time neither D.D. nor B.D., and in truth seems by his own account to have known little more of divinity than he did of chemistry seven years before. But such was his good luck, or the reputation he had established for carrying his object, whenever he took one in hand, that no other candidate appeared. The professorship when he got it was worth about 330l.; but he boasts of having raised it to more than three times that value. Not that he ever had any pretensions to call himself a learned theologian: on the contrary, he was rather vain of being spoken of as the Professor aureōrdænsis, the self-taught professor, or rather the professor who was indebted for what he knew neither to masters nor books. His constitution was, he says, ‘ill fitted for celibacy,’ so in December, 1773, he married the daughter of Sir Edward Williams of Dallam Tower, in Westmoreland; and the next day he went to North Wales to take possession of a sinecure rectory, procured for him by the bishop of St. Asaph by the duke of Northumberland, who, after his death, was enabled (also through means of his grace) to exchange for a prebend in the church of Ely. In 1780 he succeeded Dr. Plumptre as archdeacon of that diocese; the same year he was presented to the rectory of Northwold, in Norfolk, a small living, which, after his death, he left to his son, who afterwards received another much more valuable living, the rectory of Knaploft, in Leicestershire, from the duke of Rutland, who had been his pupil at the university. He was now therefore tolerably well provided for.

Meanwhile his publication not already noticed had been, in 1772, two Letters to the Members of the House of Commons, under the name of A Christian Whig, in support of the clerical petition for the abolition of subscription; in 1773, also without his name, A Brief State of the Business of the Whigs, in which he defended a restoration sermon entitled The Principles of the Revolution Vindicated, which made considerable noise, and, as he conceives, gave great offence at court and in courtly circles; the same year his well-known Apology for the Life of his late father, was published, and was immediately followed by three volumes of sermons and charges. In March, 1792, on the appearance of Soame Jenyns’s Disquisitions on Various Subjects, the toying of which annoyed him, he thought it necessary to defend his whig principles in An Answer to the Disquisitions on Various Subjects, and the present government, and gratifying the duke. Of course Shelburne professed to have selected him from his own discernment of his merits. Let that have been as it may, Watson proved a very unmanageable bishop. Neither Shelburne nor any succeeding minister could ever get him to run in harness. The first thing he did after he found the minute on his head was to publish, in 1782, A Letter to Archbishop Cornwallis on the Church Revenues, recommending an equalization of the bishoprics. This he did in spite of his party, because he said it was a thing which would embarrass the government, and at the same time do nothing to forward his object. And so he continued to take his own way, and was very soon allowed to act without much of the peremptory guidance which might have guided him or stop him. He made some good and effective speeches in the House of Lords, but never originated nor even materially assisted in carrying any legislative measure. For the most part, in general politics, he sided with what was called, the whig party; but he would not come up to vote for Fox’s Indin Bill in 1783, and he had a theory of his own upon the subject of the treatment of the House of Commons by Pitt which followed. On the occasion of the king’s illness in 1788, again, he went with his name in a minority in the House of Commons to the regency, for which it was thought at the time that he had a good chance of the bishopric of St. Asaph, then vacant; but his majesty’s recovery dissipated that along with many more such flattering visions. However before that, in 1786, Mr. Watson, who had been so unfortunate by the death, in 1796, of his friend and former pupil, Mr. Luther, of Ongar, in Essex, who left him in his will an estate which he sold for 20,500l. He grumbled on about having sacrificed himself to his principles, and being overlooked and left in poverty; but he still laboured for his professorship, and his archdeaconry, and his rectory—all, by the bye, as he managed the matter, either out of, or as nearly as possible, sinecures—in addition to the money and the profits of his various publications, his case could not well be expected to excite much commiseration.

What remains of his biography is little more than the
catalogue of his other literary performances. In 1783 he published a useful 'Collection of Theological Tracts selected from various Authors for the Use of the Younger Students in the University,' in 6 vols. 8vo., which went through two large editions. An Address to Young Persons after Confirmation,' which he published in 1783, was already valuable. The great increase in the number of Tracts since the author's death has been introduced in a new edition, with 'Considerations on the Expediency of revising the Literary and Articles of the Church of England, by a consistent Protestant,' another of his adventurous proclamations of peculiar views, which brought upon him a good deal of outside annoyance. Various Charges and sermons were delivered to the clergy of his Diocese in June, 1791, full of vituperation of the Corporation and Test Acts, and laudation of the French Revolution. Upon this latter subject, however, he soon after cooled considerably, as pet содержит, by his next Apology, a sermon published in 1793, which he entitled 'The Wisdom and Goodness of God in having made both Rich and Poor,' and which was expressly directed against the very democratic principles out of which the Revolution in France had sprung. He talks of the 'strange' turn which that great movement had by this time taken, as justifying or accounting for his apparent change of feeling about it; as if it was the course of events that had been in the wrong—not he and his an cient principles, sufficiently distinguishable from modern works, his 'Apology for the Bible, in a Series of Letters addressed to Thomas Paine.' This was followed two years after by 'An Address to the People of Great Britain,' an energetic appeal in support of the war against France. The influence of Khevenhüller's 'Anecdotes of the French Revolution' had from it came from, excited immense attention. Fourteen regular editions of it, he says, were sold, besides many pirated ones. Some years after, in 1803, he published another tract, entitled 'Thoughts on the intended Invasion,' in the same year. His last works, the majority of which were also printed by him from time to time, which need not be noticed in detail. His last publication was a selection of his fugitive pieces, in two octavo volumes, which appeared in 1816, under the title of 'Miscellaneous Tracts on Religious and Moral Subjects,' and were published with his own permission. In the last years of his life he spent mostly in retirement on his estate of Calgarth Park, in Westmorland, which he amused himself in ornamenting and improving by building and planting. He died there on the 4th of June, 1816. He had several children. After his death appeared, under the superintendence of his son Richard Watson, L.L.B., prebendary of Llandaff and Wells, the work from which the above particulars have been principally extracted, entitled 'History of the Life of Richard Watson, Bishop of Llandaff.' written by himself at different intervals, by revised in 1814.'

WATSON, ROBERT, a respectable Scotch author of the age of Hume, Robertson, and Adam Smith. Robert Watson wrote an essay upon the theory and practice of combined the professions of brewer and apothecary. Robert completed the usual courses of languages and philosophy, and commenced the study of divinity in the University of St. Andrews. He attended the Divinity Hall in Glasgow for at least one winter, and finished his theological studies in Edinburgh.

In 1751, Adam Smith having removed to Glasgow, where he had been elected professor of logic, Watson was encouraged by Lord Kames to deliver a course of lectures upon the same subject, the lectures being delivered by Smith. The reception these lectures met with encouraged him to repeat the course every winter during his continuance in Edinburgh.

In 1758, having become a licentiate, or, as it is called in Scotland, an 'ad eundem,' he advertised himself a candidate for one of the churches of his native town, which happened to be vacant. The application was unsuccessful, but Mr. Henry Rymer, professor of logic at St. Salvador's College, entertaining thoughts of retiring from public life, presented a testimonial of the writer's services to the Synod, by the payment of a sum of money, to resign in his favour. The other professors sanctioned the bargain, and elected Mr. Watson professor of logic, and the Crown soon afterwards constituted him by patent professor of rhetoric and belles-lettres, a situation he held with great reputation in the university of St. Andrews, which was that about the same time in Glasgow by Smith and Reid, in Aberdeen by Beattie, and in Edinburgh by Hlayson. He substituted for a course of lectures on logic, properly so called, a course of lectures on the theory of the human mind, on the exercise of the reasoning faculty, and on literary criticism.

In 1777 Dr. Watson, stimulated by the success of Robertson's 'Charles V.,' published (at London), his history of 'Philip II. of Spain.' The work was favourably received in England, and in France, and was translated into Dutch, and German. This success encouraged the author to commence the history of Philip III., four books of which were completed at the time of his death in 1780. A few years before his death he had been promoted to be principal of the university of St. Andrews, the birthplace of Salvador on the death of Principal Tuldewalsh. Watson left five daughters by his wife, who is said to have been a woman of great beauty, daughter of Dr. Shaw, professor of mathematics in St. Andrews college. The four completed books of the history of Philip IV., with two additional, by Dr. William Thompson, were published by that gentleman for the benefit of the author's family.

In a literary point of view the histories of Philip II. and Philip IV. are far inferior to the work of Robertson: they are heavy, not very elegant, and show nothing of a comprehensive or philosophical mind in the author. They are however impartial, but for a slight natural bias of the author in favour of the Protestant party. The narrative is full and minute. The extracts of Historians and of the English critics complain of the parade of military technicalities with which the 'History of Philip II.' in particular is overlaid; and M. de Beaumarchais points out that the transactions in the Spanish colonies, in Naples and Sicily, are carried on without reference to the particular circumstances of the 'History of Philip II.,' but he had not consulted the original authorities, and estimated the work, without reference to its accuracy or elegance, by the quantity of materials which it supplied for his imaginative pictures or political and social speculations.

(Woodhouselee's Life of Lord Kames; Chalmers's Bio graphical Dictionary—Lives of Adam Smith, Blair, and Watson; Preface to the Life of Philip III.; Biographie Universelle—Lives of Philip II. and III., and Watson; Schiller's Abfall der Verantwortung der Geschichte.)

WATT, ROBERT, M.D., is the author of a well-known work, entitled 'Bibliotheca Britannica, or a General Index to British and Foreign Literature,' 4 vols. 4to., Glasgow, 1819-1820; Edinburgh, 1824; a new edition with a few corrections of him in that work (sent to the press after his death) is that he was born in Ayrshire in 1774, that he died at Glasgow 12th March, 1810, that he was president of the Faculty of Physicians and Surgeons of Glasgow, and lecturer at the Royal College of Physicians; that he had published the following works during his lifetime:—

'Cases of Diabetes. Consumption, &c.' 8vo., Paisley, 1808;
'Catalogue of Medical Books,' 8vo., Glasgow, 1812;
'Rules of Life, with Reflections on the Manners and Dispositions of Mankind,' 12mo., Edinburgh, 1813 (anonymously); besides a few papers in the 'Transactions' of the Medico-Chirurgical and one or two other societies. We have found no account of him anywhere else.

The 'Bibliotheca Britannica' is in two parts: the first containing an alphabetical arrangement of authors, with the published works of each in chronological order: the second, a similar arrangement of subjects, with an enumeration of the books treating of them, and references to the entry of each work under the author's name in the first part. The compilation, prepared amid the calls of a professional life and without access to any extensive library, was carried through with great rapidity. In the author's own estimate of the work, there is no doubt chargeable with many positive errors, as well as with important deficiencies; but it is notwithstanding both a remarkable performance for an individual and an aid of very considerable utility in many literary investigations. It cannot be relied upon as an authority, but it is serviceable as a guide or indicator.

WATT, JAMES, 'who,' to adopt the eloquent language of the inscription placed by Lord Brougham upon his statue in Westminster Abbey, 'directing the force of an
works on surgery and medicine. He was found one evening occasion conveying into his room for dissection the head of a child who had died of some unknown disease. Leaving, however, all these studies, Watt, in 1764, took the profession of a mathematical-instrument maker. It is usually stated, without any allusion to preliminary instruction in this art, that he removed to London in 1766, to please himself under Mr. John Morgan, mathematical and instrument maker, of Great St. Mary's Church, near the South-Change. No contemporary memoir published in the 'Public Characters' of 1802-3, states that he was, at the age of sixteen, 'trained as an apprentice to learn the art of an instrument-maker, a sort of business,' it is observed, 'of which we have no idea.' From this Mr. Morgan, whose name is not now common even in Glasgow or other large towns either in north or south Britain.' At that period, we are further informed, 'this profession included the making and repairing of the instruments used in experiment in mechanics and mathematical philosophy; the manufacture, in a rough way, of all kinds of musical instruments, and of theodolites, quadrants, and other instruments necessary for the practice of land-surveying.' The account referred to does not state the place of Watt's apprenticeship, which is said to have been for three years, a period rarely exceeded in Scotland unless for the sake of obtaining certain privileges independent of the mere learning of the trade or profession; but from the narrative of Stuart it would seem that when Watt left his master, he 'took the opportunity of his visits to a maternal aunt at that place,' Watt became interested in the operations of a mechanic 'who eked out a scanty subsistence by making and repairing fishing-tackle, and the simple instruments used by the farmers in weighing and draughting farm produce.' By this means, he had 'the company of a squire, a rascal of fiddles, and a turner of spinets, he was, we are informed, a useful man at almost every thing. He retained nicknacks of many kinds, and through dealing in spectacle-glasses, he was dignified with the title of an optician.' Watt, according to this account, was not interested in Watt's generation, for he remained not quite two years. After this kind of apprenticeship, Watt removed to London, where he acquired his education and his professional knowledge, and where he remained for twelve months, when the distressing headaches thereby occasioned ceased to afflict him. It is also stated, but without any indication where, that Watt was apprenticed to John, a writer to the 'Encyclopaedia Britannica' as the author of the life published in that work, which first appeared, some years since, in the Supplement; but as the dates and other circumstances agree, there does not appear to be any reason why the name should be omitted. His father's name is referred to. The memoir by his son merely states that the desire of improvement in an art then little practised in Scotland, induced young Watt to visit London (according to this account in his eighteenth year), where however he remained little more than two months, when the infirm state of his health compelled him to return to the parental roof.

Shortly after his return from London, Watt endeavoured to establish himself in business in Glasgow, but, owing to his having been a burgess, he was not admitted to the corporations of arts and trades, which considered him an intruder upon their privileges, and refused to allow him to set up even the humblest workshop. From this difficulty he was extricated by the interposition of the authorities of the University of Glasgow, a corporation which, in the twelfth year of the present century, the University offered him an asylum within their precincts, where they permitted him to establish a shop; and they also honoured him with the title of their mathematical-
WAT

Instrument maker. These circumstances happened about the year 1797, when Watt had scarcely attained his twenty-first year; and it appears that he was especially indebted, for the friendship shown by the authorities of the University to the kind offices of Adam Smith, author of the 'Wealth of Nations,' Dr. Black, Robert Simson, the eminent mathematician, and Dr. Dick, professor of natural philosophy. In this profession Watt displayed much ingenuity and manly dexterity; and his superior intelligence led the way to the solution of many difficult problems. Watt was a skillful artist, to form habits of intimacy and friendship with him, so that his workshop became a favourite resort for the most eminent scientific men at Glasgow. His intimate friendship was established with that great man, Dr. Robison, who, resembling in his pursuits the investigations in mathematical and mechanical philosophy, in an unpublished MS. used by Arago, expresses the surprise which he felt when, on being introduced to Watt, whom he expected to find merely an intelligent workman, he found a philosopher, as young as himself, yet willing and able to instruct him, or any of the students who might fall into difficulties. He needed but prompting to take up and conquer any subject; and Robison states that he learnt the German language in order to peruse Leibnitz's 'Treatise of the Form of Steam in the Mariner.' But Robison was a problem on which he was engaged seemed to require it; and that similar reasons led him subsequently to study Italian. Without neglecting his business in the daytime, he had laboured for nights and often worn instruments; and the spirit of inquiry which was a characteristic of his mind, was a most vivid impression, it seems to have recommended to it his indefatigable character. In illustration of this characteristic of his mind, it is related that he undertook and accomplished this book of 200 pages on a subject which has been said to be totally insensible to the charm of music that he could not distinguish one note from another. His instrument was no less remarkable for its harmony than for several important improvements in its mechanical details; and it is believed the piston cylinder was invented by Watt, respecting the theory of temperament in music, a matter then very little understood, and of which he could have gained no knowledge except through the profound but very obscure work published on the subject by Dr. Robert Smith.

The earliest occasion on which the attention of Watt was seriously directed to the properties of steam appears to be that mentioned under STORM-CARRIAGE (vol. xxii., p. 460); and his son states that about 1761 or 1762 he tried some experiments on the form of steam in the carriage of a known as Papin's digestor; and constructed and worked a small model, consisting of an inverted syringe, the bottom of the rod of which was loaded with a weight; alternately admitting the steam into the space between the rod and the atmosphere. Thus he practically demonstrated the power of steam used as in modern high-pressure engines; but he soon abandoned these experiments, and he appears to have entertained a prejudice against the use of his invention in its principal application to a machine, respecting the theory of temperament in music, a matter then very little understood, and of which he could not have gained no knowledge except through the profound but very obscure work published on the subject by Dr. Robert Smith.

The event to which the commencement of his invaluable discoveries may be most distinctly assigned, took place in the winter of 1768-9, when Professor John Anderson, who occupied the chair of natural philosophy in the university of Glasgow, requested him to examine and repair a small model of Newcomen's steam-engine, which could never been made to work satisfactorily. His sagacity led him to discover and remove the defects of this model, which was subsequently used in the class-room; and by this circumstance Watt was impressed by the imperfections of the steam-engine itself, and to investigate those properties of steam upon which its action depended. About this time he left the college and took up his abode in the town previous to his marriage with his cousin, Miss Mitchell, in the summer of 1769. Watt went with Dr. Cleland to endeavour to find the house, near the harbour of Glasgow, to which Watt retired to follow up his important experiments, but found it pulled down, its site being, appropriately enough, occupied for the manufacture of colonial steamboats.

By referring to the article STORM-ENGINE (vol. xxii., p. 474), where the action of Newcomen's machine is described and illustrated by a diagram, it will be seen that its arrangement was made up of two distinct conditions: first, that when the cylinder was full of steam, a degree of coldness should be produced within it that should occasion the sudden condensation of the steam, and thereby produce a partial vacuum beneath the piston, which should cause the atmospheric pressure on its upper surface to force it down, with sufficient rapidity to give motion to machinery for working a pump; and secondly, that immediately after the completion of one stroke the temperature of the cylinder should be again raised to such a degree as to enable it to become refilled with steam preparatory to another stroke. A considerable amount of steam was required, called in by circulating water, for this purpose. Watt perceived that the cylinder was too hot to allow the immediate condensation of the steam just admitted, time was lost in cooling the cylinder; and, thirdly, the loss of heat from this radical defect of the old, or, as it is usually called, the "steam" atmosphere, was three times as much as was applied to the efficient action of the machine. Such was the best, perhaps it is not too much to say, and the only efficient steam-engine used before the time of Watt; and notwithstanding its wasteful expenditure of fuel, it was extensively used for the purpose of draining mines. It was thus applied in the collieries in the north of England, in the tin and copper mines of Cornwall, and in the steam-vessels navigated by the Hudson and Mississippi rivers, and in the steam-machines of Cumberland. Shortly after the middle of the eighteenth century it was applied to the purpose of raising water to turn water-wheels, and it was also used for the working of blast-furnaces for smelting iron ore, and in a few cases for raising water for the supply of towns; but its use was necessarily limited to a small cost of working, as well as by its defective and clumsy construction. Watt perceived that it was desirable, in order to the efficient use of the steam, that the cylinder should be kept hot as the valve opened; and to provide for this he had recourse to the beautifully simple expedient of condensing the steam in a separate vessel, which might always be kept cool, and between which and the cylinder a communication might be opened whenever it was required from the condenser. A certain range being perfected, he next devised means for deriving the fullest possible advantage from it, by maintaining a uniform and high temperature in the cylinder; an object which he accomplished by enclosing its upper part in a jacket, or outer casing, and filling the intervening space between its inner and outer casings with steam, and the exchange of heat between the two is given under STORM-ENGINE. The invention was in its main features completed as early as 1765; and in the course of his early experiments Watt was much struck by the great heat communicated to the injection-water by the steam, and the quantity of steam, a circumstance which led him by further trials to the discovery that water converted into steam would heat about six times its own weight of water at 47° or 48° to 212°. Being struck with, and not understanding the reason of, this remarkable fact, as he himself states in the notes to Robison's "Mechanical Philosophy," Watt mentioned it to his friend Dr. Black, who then explained to him his doctrine of latent heat, which he had taught some time before, although he had neither heard of it, or not attended to it when he thus, to use his own word, "stumbled upon one of the material facts by which that beautiful theory is supported. In order to correct an erroneous statement which had been obtained with regard to its action, we insert a further quotation from the above notes, where Watt observes—Dr. Robison qualifies me as the pupil and intimate friend of Dr. Black, and goes the length of offering to me to have profited to owe my steam-engine to the instruction and information I had received from him, which certainly was a misapprehension. He is also mistaken in his assertion that I had attended two courses of the Doctor's lectures. The following observations upon my steam-engine to the instruction and information I had received from him, which certainly was a misapprehension. He is also mistaken in his assertion that I had attended two courses of the Doctor's lectures. The following observations upon my steam-engine to the instruction and information I had received from him, which certainly was a misapprehension. He is also mistaken in his assertion that I had attended two courses of the Doctor's lectures. The following observations upon my steam-engine to the instruction and information I had received from him, which certainly was a misapprehension. He is also mistaken in his assertion that I had attended two courses of the Doctor's lectures. The following observations upon my steam-engine to the instruction and information I had received from him, which certainly was a misapprehension. He is also mistaken in his assertion that I had attended two courses of the Doctor's lectures.
which had compelled him to establish himself in the pre-
minets of the college, his wife being the daughter of a free-
man. Being thus rendered a freeman himself, he opened
a chandler's shop, and among the increasing business led
him to require the labours of an assistant. The success of
his first experiments induced Watt to determine upon the
construction of a larger model than could be conveniently
and privately constructed at his usual place of business,
and he planned with this view, in 1761, a machine which
had a cylinder of nine inches diameter, and which, as
far as it was worked, proved satisfactorily the practical
importance of his improvements; and as neither his leisure
nor his means enabled him to proceed, the project was for
a time dropped.

In addition to his employment as a mathematical in-
strument maker, Watt devoted much time to the practice
of land-surveying, and this led to the employment of his
superior talents in the more important departments of
civil engineering. Such projects as appear to have oc-
ccupied much of his attention between the year 1765, when
the leading features of his invention were perfected, and
1768, when he found in Dr. John Roebuck, to whom he
had become known as a surveyor, an individual capable
of appreciating the practical value of his invention, and
of sufficiently entering to support him in further experi-
ments. Dr. Roebuck, who is perhaps best known as the founder
of the Carron-works and the vitriol-works at Preston-
pon-Ravens, was engaged in an extensive colliery un-
taking at Kinneil, a few miles from the Carron; and an
outbuilding connected with his residence Watt com-
mented, in the winter of 1768, a third model, on a much
larger scale than either of the preceding. This engine had
a cylinder of block-iron, eighteen inches diameter, and its
construction many difficulties had to be overcome,
raising partly from inexperience as to the proportions
of the several parts, but mainly from the imperfect work-
manship unavoidably during the infancy of the art of machine-
making. Watt arranged the cylinder in the stoutest con-
packing of the piston, which could not be effected, as in
the old engines, by covering it with a body of water.

At length, after eight months' labour, Watt and Roebuck
had the satisfaction of seeing the machine in successful op-
eration. The saving of fuel was enormous; the saving
effected in the supply of water for condensation was little
less important, and the result of the experiment fully sat-
isfied Roebuck, who obtained a share in the patent by
which Watt secured his inventions. This patent had been
applied for in 1765, but not before the expiration of eight
years, and it was obtained on the 5th of January, 1769.*

In the summer of that year however the mining specula-
tions of Roebuck involved him in such embarrassments that
he was obliged to abandon the steam-engine, and Watt himself was therefore obliged to return
to his former avocations as an engineer and surveyor (he
having relinquished the business of instrument-making in
1768), and to such engagements he chiefly devoted himself
until the close of the year 1773. Among the surveys and
engineering works in which Watt was engaged before he
finally devoted himself to the carrying out of his improve-
ments on the steam-engine was a projected canal between
the Forth and the Clyde, by what was called the Lenond
project. Watt was engaged in it, when his attention was
engaged on similar surveys upon a rival line. He also
planned and superintended the execution of a canal for
conveying the produce of the Monkland collieries to Glas-
gow. He was engaged upon the Crinan canal, which was
subsequently abandoned by Roebuck, and Watt himself, and
the river Clyde, improving the navigation of the Forth
and Devon, and the Water of Leven; a canal from Mach-
hiiiian Bay to Campbeltown; another from the Grand
Canal to the harbour of Borrowtounness; improvements
in the harbours of ayr, Port Glasgow, and Greenock; and
the building of bridges at Hamilton and Rutherglen. He
was among the engineering works and improvements with
which he was connected. Business of this description crowded
upon him, and it is stated, in the "Encyclopædia Brittanica,"
that his reports are quoted for their perspicacity and
accuracy. In his surveys he used an improved method of
amplification, in Brebner's "Edinburgh Encyclopædia," article "Watt," and also a machine for
drawing in perspective, both of which he had himself in-
vented. It was while engaged on the greatest engineering
works that he undertook himself with this engine on a line
which had a cylinder of nine inches diameter, and which,
as far as it was worked, proved satisfactorily the practical
importance of his improvements; and as neither his leisure
nor his means enabled him to proceed, the project was for
a time dropped.

* The above date is taken from a chronologically arranged list of patents relating to the steam-engine, printed at the end of Mr. Watt's "Anecdotes of Steam-Engineers;" and is corroborated by his statement, published in his "Anecdotes," p. 248, 249 of that work, that the patent was procured in consequence of the improvements which were embodied in his last engine. Among the brief summaries of Watt's list of patents, the objects embraced in this are as follows: "Exhausting atmosphere from cylinders—keeping cylinder hot as the atmosphere—expelling steam from a passage newly arranged in Watt's engines—admission produced in separate valves—air extracted from condenser by pumps—platinum gained by the steam—steam wheel (of rotary engine)—partial condensation of steam—using oil and wax, instead of water of steam;" (Anecdotes, pp. 697.)

---

Roebuck, to whom Dr. John Roebuck transferred his share
in the property of Watt in 1764, was a man excellently
qualified to bring it into profitable operation; his energetic
and business-like habits supplying what was wanting in
the character of Watt to cope with and eventually to con-
quer those moral obstacles which, more than any other
thing, retarded the introduction of the
Proper steam-engine an arduous undertaking. He also
possessed in his works at Soho mechanical facilities of a
superior order, as well as a large capital to establish the
manufacture. Watt's improvements were observed by Stuart,
* to a man like Watt, so unfitted, from feasting and habit, to stand alone, nothing could have been
more suspicious than his gaining the protection of two such
men (as Roebuck and Boulton) in succession. Obstacles
were seen to be overcome, and they both possessed, in an eminent degree, the master-art of influsing
into all around them a portion of their own matchless
energy. Projectors themselves, they were considerate of
their feelings, and knew how much the flow of thought
in Watt's mind, when he had once got his mind on a
project, was as much an art as it was a business. Assisted by their experience, and animated by their
generous approbation of what he had already
achieved, he was roused and carried onward to impart
greater perfection to his mechanism. Watt's connection
with Boulton commenced early in his year 4, and
they remained in partnership until 1806, when Watt retired
from business; but their friendship continued undiminished
until Boulton's death, after which Watt expressed, in his
notes upon Robinson's account of the steam-engine, his
highest esteem for Bay, in the passage quoted under
Boulton, vol. v., p. 274.

By the latter end of 1774, Watt completed at Soho, with
all the facilities afforded by the expert artisans under Boul-
ton, the last improvements which he had committed
his faith to. The engine was then exhibited to a deputation from the Cornish miners, and to
other persons competent to judge of its performances,
which were deemed highly satisfactory. Perfect however
was as the action of the improved machine, the patentees
knew that much remained to be done to bring it into
extensive operation; that costly machinery must be con-
structed to assist in the fabrication of the new engines;
and that a protracted struggle with ignorance and prejudice
was to be anticipated before any remunerative return could
be expected. Watt, when the engine was ready for public
exhibition, gave his patent, which had been granted for
years for which the patent was granted had already elapsed,
but it did not appear probable that the remainder of the term
would suffice for the reimbursement of past and prospex-
tive expenses; while there was no doubt that, the prelımi-
nary improvements in the disposition of the cylinders,
and in the construction of the improved engines would imme-
diately follow the termination of the exclusive privilege
held by Watt and his partner. They therefore immediately
applied for an extension of the term of their patent;
and, although the application was made at a time when
hostility was so severe and determined, was as a
violent opposition, in which Edmund Burke took part, "not,"
" as observed by Muirhead," from any hostility to Mr. Watt
or his patent, but simply from a sense of duty in defending
their interests, or what they conceived them to be,
the claims of a constituent," and which occasionally
arose from the expense and anxiety to the patentees, it was ultimately suc-
cessful, an act being passed in 1775 (16 Geo. III., c. 61),
vesting in James Watt, engineer, his executors, administrators, and assigns, the sole use and property of certain steam-engines, commonly called fire-engines, of his invention, described in the said act, throughout his majesty's dominions, for a period of twenty-five years from the passing of the act. Being thus assured a return for their outlay, the patentees prepared for the manufacture of steamengines on the most extensive scale, and with a degree of accuracy never before attempted in the art of machinery. In order fully to comprehend the difficulties conquered by Watt, it must be remembered that his machine required much more accurate workmanship than those used in the manufacture of clocks. James Boulton, the son of his partner, at the meeting held at Freemasons' Hall in 1829, for erecting a monument to Watt, at the period of the construction of the first steam-engine upon his principles at Soho, the intelligent and judicious Standard was to be invited to satisfy himself of the superior performance of the engine by his own experiments upon it, and had been convinced of its great superiority over Newcomen's, doubted the practicability of getting the different parts executed with the requisite precision, and suspected, from the extreme difficulty of attaining this desideratum, that this powerful machine, in its improved form, would never be generally introduced.'

Stuart states that when the engine tried at Kinnel was made by two artists who could give the requisite truth of workmanship to air-valves and cylinders of two inches diameter; while Watt required similar accuracy in cylinders of many thousand times their capacity, and in the large pistons, piston-rods, and other working parts.

The opposition raised to an extension of the patent had the effect of exciting the public attention, and the commercial tact of Boulton greatly facilitated the introduction of the machine to general use. Pursuing throughout an enlightened and liberal policy, the partners invited the public to an inspection of the engine, freely explained the principles of its action, and promoted a series of experiments under the inspection of practical and scientific mechanics whose professional character and position in society placed them in a position to be able to speak with authority of the advancement of science and manufacture, when the means were made, before the same persons, on an engine of Newcomen's construction, of the best make and in perfect order; and the results as to quantity of coal consumed, and amount of work done, in a given time, were contrasted. Thus the immense saving effected was rendered manifest to the parties to whom the use of the machine was recommended, and the remuneration of the patentees was made proportionate to that saving. Without attempting to realize their profit as manufacturers of the engines, Watt and Boulton thought it necessary to continue the act as far as the value of one-third of the parts saved by using their improved machine instead of the old fire-engine. After paying this very moderate claim, it cost little more than half the money previously paid for an engine in pumping water, which was far more than the wages of work, labour, and receiving the great saving of room, water, and repairs. Not only were the engines supplied, at certain fixed prices, according to size, at such a rate as would have been charged by any neutral manufacturer; but where persons were either unable or unwilling to throw aside the expensive apparatus which they might have already in operation, the patentees took the old engines in part payment for the new, often at rates far beyond their real value; while in other cases they erected machinery works, and were enabled to have engines on order when they produced the estimated advantage. In some instances parts of the old machinery were brought into use, as, for instance, by placing a smaller working-cylinder within the old one, and using it as the outer case or jacket; while in others, half the size of the old one, the power of the machine was so augmented as to present a striking illustration of the value of the patented improvements. Still further to facilitate the adoption of the new machine, it was agreed that upon terms which its use was allowed as clear as well as liberal as possible, the patentees laid down a standard of horse-power by which to calculate the power of their machines; and in so doing their honourable spirit was rendered strikingly apparent. It is evident that this was a standard of horse-power, which would have increased the apparent value of their engines, they estimated the power of a horse as equal to raising 30,000 lbs. one foot high in a day, while Smeaton had valued the force of a strong English horse as low as 20,000 lbs.; and they moreover calculated their machinery so as to perform work equal to raising 44,000 lbs., a foot high for every man and horse placed by it, so that, in fact, what they called a free-horse-power engine would perform as much as ten horses according to Smeaton's estimate. Even these liberal terms and modes of computing the power of their machines might have proved insufficient to effect their object, had not they provided, in all cases, a satisfactory check upon the use of every species of fraud, by which, as was generally represented as doing more or less than they really did perform, Watt contrived an apparatus for counting and registering the strokes of the great lever or beam of the engine, and thereby affording uncensored and indisputable data for computing the duty performed. This apparatus, or counter, was looked up in a box with two keys, one of which was kept by the proprietor of the engine, and the other by the patentees, who employed a confidential agent to open and examine the apparatus, in the presence of the proprietors, every three months.

Of the spirited manner in which Boulton conducted the mercantile department of the great adventure some idea may be formed from the fact, that upwards of 74,000 lbs. was paid to him before the year 1790 began, but at length their remuneration began to pour in, and in no scantly stream. In Cornwall and other mining districts, especially where coal was not abundant, the new engines would frequently replace the old. At the agreement the patentees agreed to receive a fixed sum, lower than the amount that would have been payable to them under the usual agreement, in lieu of the stipulated rent, they soon realized a very large annual revenue. In one instance, in one mine, in which three very large engines were employed, the proprietors agreed to pay 800 per annum for each engine as a compromise for the patentee's share of the saving of fuel.

The chief application of the old atmospheric engine, and also of Watt's first invention, was pumping water, for the purpose of pumping water from mines, a purpose for which the circumstance of its power being applied only during the downward stroke of the piston was of little consequence. As, however, the extension of manufacturing operations called for the introduction of some powerful and manageable prime-mover, more uniform in its action and less dependent upon local circumstances than either wind or water, various attempts were made to apply the steam-engine to this purpose, for which, in most cases, it was necessary to turn the power into a uniform direction, by giving its descent from which it might turn a water-wheel. A large atmospheric engine was erected for this purpose, in 1752, at Champion's copper and brass works, near Bristol; and such engines were subsequently introduced at several other places, among which was the Cornwall works. Watt was fully aware of the importance of some more convenient method of obtaining rotatory motion from the steam-engine; and of the numerous plans which had either been tried by others or were suggested by his own fertile imagination, he determined to have an engine which should be able, if necessary, to be stopped against the whole of the crank, the efficiency of which was shown by its use in the lathe, the knife-grinder's wheel, and other machines in common use long before its application to the steam-engine was thought of. A difficulty connected with the application of the crank to the single-acting engine, or that which exerted power in the downward stroke only, because it would have been necessary to use a very heavily-loaded fly-wheel to keep up and equalize the rotation imparted by the steam, was in some cases thought to avoid which Watt once proposed to employ two engines, working distinct cranks on the same axle. Watt however was not the man to publish his inventions until he had brought them to a considerable state of perfection; and he was frequently in the habit of only allowing a few men who were anxiously watching to obtain, by the most unscrupulous means, a share in the advantages of his ingenuity, were enabled to steal a march upon him. While his attention
was directed to other important points, patents were obtained, in or about the years 1779 and 1780, by persons named Waskrough and Pickard, for obtaining rotary motion from a steam-engine, the plan proposed by Pickard being the simple crank and fly-wheel. Since it appears probable that the idea was communicated through a work employed by Watt, it is likely that this patent might have been overturned; but as Watt did not think fit to contest it, he used, during the continuance of Pickard's patent, his own invention of the double-acting engine and its steam-engine with the condensation of steam—to determine the source of the air appearing when water was acted upon by the steam, the investigation of Watt was to ascertain how the steam condensed, and the law by which the efficacy of steam increased with the temperature: labour, time, numerous and difficult experiments, were required for the ultimate result; and when his principle was obtained, the application of it to the newociations of the steam-engine demanded a new species of intellectual and experimental labour. He engaged in this with all the ardour that success inspires, and was obliged to bring all the mechanical powers into play, and all the resources of his own fertile mind in exertion; he had to convert remained stationary into rotatory motion, and to invent parallel motion. After years of intense labour, he obtained what he wished for; and at last, by the regulating centrifugal force of the governor, placed between the beam and eccentric, the mathematician, and gave perfection to a series of combinations unrivalled for the genius and sagacity displayed in their invention, and for the new power they have given to civilized man.

It is pleasant to turn from the record of the meeting at which Davy thus joined with others among the most eminent men of his time in doing honour to the memory of the great engineer, to the narration of the disgraceful measures by which, not many years before, it was attempted to prevent the rival of Watt from reaping the advantages of his own improvements among the Cornish miners, who were deriving the greatest advantages from his machinery, and would in many cases have been compelled to abandon their works but for its giant aid, there were men who grudged to pay him the value of his inventions, and ventured to suppress, during which they were generously and powerfully assisted, according to Arago, by Colonel (afterwards General) Roy. Mylne, the engineer of Blackfriars Bridge, Herschel, Delou, Baedeker, Robinson, Morden, Bennett, Summer of the mechanical, and gave perfection to a series of combinations unrivalled for the genius and sagacity displayed in their invention, and for the new power they have given to civilized man.

WAT.

[The text continues with historical and technical details related to the steam engine and Watt's contributions.]
description of the machine as made by Boulton and Watt twenty years afterwards. The principal distinguishing features of the engines of Watt were the separate con-
denser and the helical cylinder; and these being retained in all his machines, gave him a virtual monopoly in various subsequent improvements which were rather additions to than modifications of his original design, but which were too essential to the engine to be separated from it. Yet, as observed by Stuart, 'After a series of experiments, in which he had been engaged for twenty years, to develop his ideas, the splendid result of his genius and perseverance—the per-
fected machine—was only to give the drawings and tables to prove that between the years 1789 and 1800 the engines which were sent from Soho were more perfect than could be fabricated from the description he gave of the one he erected in 1769.' Bramah, whose own distinguished ingenuity and practical acquaintance with the subject, joined with his high integrity and regard for truth, ren-
dered him a dangerous adversary, was enlisted among the determined opponents of Watt's patent, which he attacked solely on the ground just stated; while his printed letter to the judge who presided at the trial on which he held appeared as a witness, is referred to by Stuart, as being among a series of admissions of the value of Watt's contrivances, in which he 'points out inventions that had not been noticed or observed by others, with all the fine feeling of what is beautiful in art, and in which he was the master,' while 'he ceases not to importune to ask if the inventor has described these in a proper manner; and he comes always to the same conclusion, that he has not, and that therefore he is entitled to the superintendence of his work.'

At length, after a series of trials extending from 1792 to 1798, a unanimous and clear deci-
dion was given, fully vindicating and establishing the rights of the patentee. On this last occasion Mr. Rous, who acted as counsel for the patentees, delivered a speech, which was afterwards published in the form of a pamphlet, and in which he at once keenly satirized and overthrew the argument insisted on by the opposite party, that Watt had invented nothing but ideas; asking whether it could be supposed, in the circumstances, that he had left the undertaking, which, from the great superiority of the new over the old process, bid fair to be highly profitable, but this the French chemist declined. Another circumstance indicative of the usefulness of Watt's talents is the con-
struction and establishment of the proposition of his of Patents, and on the manner of obtaining them in large quantities.' This was published at Bristol in 1795; and about the same time appeared two or three editions of a Description of a Pneumatic Apparatus, with directions for performing the Experimental Airs.

Of Watt's success in the discovery of the composition of water, an investigation in which he, Cavendish, and La-
vosier, were engaged about the same time, very little can be said here. Referring those who are curious upon this subject to the proper works of the two last-named men, we are able to give any interesting particulars of Watt's engagement in the topic, for the undertaking was left with Arago in his Life or "Éloge" of Watt, and to the 'Historical Account of the discovery of the Composition of Water,' by Lord Brougham, illustrated with notes by the son of Watt, which is published as an appendix to Arago, "may suffice to observe that the great and pressing claims of Watt's professional avocations, together with his modesty and retiring habits, may in a great measure account for any difficulty that may arise in tracing the progress and extent of his discoveries in this, by no means minor of the many subjects to which he addressed his comprehen-
sive mind."

After retiring from business, Watt was with difficulty drawn into any undertaking, although on several occasions an appeal for engaging him was made. In 1809 the fertility of his inventive powers was shown by a beautiful solution of a difficult problem laid before him by a water-company at Glasgow, who, after establishing their works upon one side of the river Clyde, discovered that the water of very low quality was not fit for human consumption. He suggested a kind of natural filter on the other side, if they could over-
come the difficulty of laying a main from their pumps across the bed of the river. Watt contrived for this purpose a flexible iron pipe, the pieces of which were connected by a kind of bell-and-socket joint, of which he took

* In the article Boulton, Thomas, vol. iv., p. 129, it is improperly stated that John Kay was the person who resided in the founding of the Pneumatic Institution.
the idea from the tail of a lobster. The main was constructed from his designs in the following year, with the most complete success; and it forms a large tube about a thousand sand feet long, and two feet in diameter, capable of bending and applying itself to the irregular bed of the river. (Water Works, p. 125.) In another case, late in life, Watt was prevailed upon, by the solicitation of the Lords Commissioners of the Admiralty, to design a steam engine for the Board, and to give, with Captain Huddart and Mr. Jessop, an opinion upon works then being carried on in Sheerness dockyard, and upon other projected works designed by Messrs. Rennie and Whidby; and on this occasion he received the thanks of the Admiralty for authorizing the publication of the project, and for the encouragement given to the latter, especially in the design of a steam engine, for the propulsion of vessels. In 1814 he yielded to the wishes of his friends, of Brewster especially, by revising the articles 'Steam' and 'Steam-Engine,' contributed by Robinet to the 'Encyclopedia Britannica,' and enriching them with valuable notes, which were published with the collected discourses of Robison's articles, which appeared under the title of 'A System of Mechanical Philosophy.' The last project to which Watt devoted his attention, and which he appears to have very nearly perfected when he died, was a machine for copying sculpture, with which he had proceeded so far as to execute several specimens, which he presented to his friends as the early attempts of a young artist entering his thirty-third year. Having suffered so much, in other cases, from communicating his ideas to others, he expressed great solicitude that this project might be kept strictly secret; but when he had proceeded sufficiently with his design to contemplate obtaining a patent, he found that another person in his neighbourhood, who appears to have been entirely unacquainted with the other project, had been engaged in a similar undertaking. That proposal was subsequently made for obtaining a joint patent, but Watt was unwilling, as so advanced a period of life, to embark in such an undertaking.

About the year 1770 Watt had purchased an estate called Newhouse, near Lanark, where he died in his life, and he had also a property on the banks of the Wye, in Wales. His health improved in his latter years, and his intellectual faculties remained unimpaired to the last. It is related that, when upwards of seventy, he imagined that in his穀turn ascended, and gave them the task by undertaking some new study. Having selected the Anglo-Saxon language for this experiment, he mastered it with a facility which proved that there was little ground for his fears. At length, however, in the month of June, 1801, when he had passed over the 23rd of August in that year, he died, in his eighty-third year,—his last illness having been one, observes his son, rather of debility than of pain. Respecting the members of the Arago states, we are left in ignorance of the circumstances and cheerful disposition of his first wife rescued him from the depressing ingenuity and nervousness from which he had suffered so severely; and that, without her cheering influence, he might never have published his inventions to the world. In chiding for having husband and wife, and her surviving children, James, the son frequently referred to in this article, and a daughter, who married Mr. Miller, of Glasgow. By his second wife, who died in 1832, he had two children, neither of whom survived him. One of these, Gregory Watt, distinguished himself by his geological investigations, but died in 1804, at the early age of twenty-seven. As might be expected, this bereavement affected Watt very keenly; but Muirhead states that his remarkable activity of mind was not impaired, nor was his intellectual vigor lessened by the melancholy event; and that neither her conversation nor his correspondence betrayed any approach to the remarkable silence which Arago states to have been observed in the latter part of Watt's life.

Of the private character of the great engineer a most pleasing account is given by Lord Jeffrey, who, after stating that, independently of his great attainments in mechanics, he was an extraordinary, and, in many respects, a wonderful man, declares that he possessed so much and such varied and exact information—he had read so much, or remembered what he had read so accurately and well. He had infinite quickness of apprehension, a prodigious memory, and a certain rectifying and mathematical mode of understanding, which enabled him to extract something precious out of all that was presented to it. His stores of miscellaneous knowledge were immense, and yet less astonishing than the command he had at all times over them. It seemed as if every subject that was casually started in conversation with him, had been that which he had been occupied in studying and examining, such was the copiousness, the precision, and the admirable clearness of the information which he poured out upon it without effort or hesitation. In social conversation he allowed his mind, like a great encyclopaedia, to be opened and closed at pleasure, either enriched upon the occasion, to his associates; and he made everything so plain, clear, and intelligible, that, it is remarked, scarcely any one could be conscious of any deficiency in their capacity in his presence. With all this flow of information, his conversation was yet occasionally made up of few words, and the indications of talent, or who applied to him for patronage or advice. As his death approached, he was perfectly conscious of his situation, and calm in the contemplation of it, expressing his thankfulness for the length of days with which he had been blessed, for exemption from most of the infirmities of age, and for the calm and cheerful evening of life which he had been permitted to enjoy after the honourable labours of the day had been concluded. The public had only expected to lost his country, it was intimated to Watt a few years before his death, by a friendly message from Sir Joseph Banks, that, to use the words of Muirhead, 'the highest honour usually conferred in England on men of literature and science was conferred upon him,' and, in a similar vein, his proposal to erect a statue to him, while he felt flattered by the intimation, he determined, after advising with his son, to decline it. He became a member of the Royal Society of Edinburgh in 1794, of that of London in the following year, of the Saratov Society in 1810, and in 1814 of the 'Académie des Sciences' of the Institute conferred upon him the highest honour it can bestow, by electing him one of its eight foreign associates. In 1826, by a spontaneous vote, the University of Glasgow accorded him the degree of Doctor of Laws; and in 1824 a subscription was entered into for erecting a statue to his memory in Westminster Abbey, and a public meeting was held at the Freemasons' Tavern to do honour to the man who had taught us to wield, as it was then observed, the mighty instrument even in the hands of but a few men, and whose inventions were characterized by Davy as amongst the great means which had enabled Britain to display power and resources, during a long war, so infinitely and invarably, he might have been extricated from the physical strength of her competition. After the event, immediately raised, and Chantrey was engaged to furnish the statue, which is one of the finest of his works, and which calls to mind the remark of Watt's friend, Mr. Gray, 'When he heard the news, he asked his friends to contemplate an Art which, without fancying that he beheld the personification of abstract thought. To this an appropriate inscription by Lord Brougham was added. Another statue by Chantrey adorns an elegant chapel erected by Watt's only surviving son, at the parish church of Handsworth, near Birmingham, in the chancel of which he was interred. Other statues have been erected in St. George's Square, Glasgow; in the University of Glasgow, where the memory of Watt is also preserved by an annual prize which he established, the 'James Watt Prize;' the society devoted to the advancement of science and the arts; and in a public library at Greenock, which is enriched with a collection of scientific works presented by Watt during his life, and to which his son contributed liberally.

In 1834 M. Arago read to the French Académie des Sciences the 'Historical Eloge' to which allusion has been repeatedly made in this article, and which reflects much honour on the liberal feeling of the author. He has been presented in full in our first edition; in this translation we have chiefly referred to is that of Watt's relative, James Patrick Muirhead, Esq. M.A., published in 4to. in 1839, to which some valuable notes are added. Of other authorities referred to for the purpose of this memoir, mention may be made of the 'Memoirs of Watt' in the 'Encyclopaedia Britannica,' 'Brewster's Edinburgh Encyclopedia,' and the 'Public Characters of 1802-3,' together with the printed 'Proceedings of the
public meeting above referred to, are among the principal.

WATTEAU, ANTOINE, a celebrated French landscape-painter, was born at Valenciennes in 1684. He went to Paris at 1705, with the forgiveness of God, he had placed himself, and for some time was occupied in that branch of painting. But after some time his master left Paris, and Watteau was obliged to seek another employer: he for a short time found occupation as a copyist, and then as a reporter. By his improvement however he was soon rescued by Claude Gillot, a painter of some ability, who having perceived the peculiar genius of Watteau, took him into his house and employed him as a painter, writer, and by this employment the genius which he was soon rescued by Claude Gillot himself, that he forsook painting and took to engraving. Watteau now required repARATION rapidly: he was appointed peintre de fête galantes du Roi, and was elected a member of the French Academy of Painting. In 1718 he came to England, where he remained a year; but he painted only two pictures during his stay, for Dr. Meade, whom he came to consult, says Walpole. He returned to Paris in a very weak state of health, and died at Nogent, in the neighbourhood, in 1721, aged thirty-seven.

His colouring was rich, and his design, though peculiar, was the envy of his family at Stoke Poges, where his pictures are chiefly theatrical scenes, or fêtes champêtres, and were remarkably popular in his time: nearly all the French engravers of his period were occupied with the works of Watteau. The prints after his works amount to 320, and it was at his house that French painters in a short life have done so much as Watteau.

As regards the particular style of his works, Watteau is generally allowed to have had an injurious effect upon the taste of the French artists of his time: his pictures generally represent a shepherdess, shepherd, and®-scape-painter, public compositions, with grotesque figures, figures, satyr, &c., and confirmed Watteau in the same style; but the pupil soon surpassed the master in his own style, and this was so evident even to Gillot himself, that he forsook painting and took to engraving. Watteau's works are excellently rapid: he was appointed peintre de fête galantes du Roi, and was elected a member of the French Academy of Painting. In 1718 he came to England, where he remained a year; but he painted only two pictures during his stay, for Dr. Meade, whom he came to consult, says Walpole. He returned to Paris in a very weak state of health, and died at Nogent, in the neighbourhood, in 1721, aged thirty-seven.

like a shock of corn in his season, he extended into the regions of perfect and immortal life and joy.

The tenor of the remainder of Watt's life was uniform. Sir Thomas Abney had been bred up in dissenting principles; King William knighted him; and he served the office of Lord Mayor of London in 1700. His first wife was a daughter of royl, the first pastor of the Mark-lane congregation; his second, a daughter of Mr. Gunston, an honoured friend of Watts. The house of the Abneys at Theobalds adjoined the site of Burleigh's residence. Of the splendid gardens of that palace there remained little which Watts was not beguiled by two rows of elms, and within a few yards of the entrance of that walk there stood, in Sir Thomas Abney's garden, a summer-house, which, fifty years after Watt's death, was almost in the same position in which he wrote some of his works. Watts's usefulness among his flock was in no wise diminished by his residence at Theobalds. There was a carriage at his command when his health permitted him to officiate in London. When he was incapable of public labour, he refused to receive his salary; and at all times a third part of his income was devoted to charitable uses. The seasons when indisposition incapacitated him from public duty were spent in literary composition. Perhaps, Dr. Southey has justly observed, 'the peculiar position in which he was placed gave to his mind and the affection with which his congregation regarded him. It made him independent of them; and they looked upon him not in the light of a dependent upon the wealthy family with which he was domesticated, nor as a humble fact, but in the reality that was in the religious faith. He adopted it by the especial friendship of one of the wealthiest and most considerable persons attached to the dissenting cause.' Moreover, the congregation felt that the service to which his health would permit, Mr. Watts conferred upon them a favour and a kindness which could not be imputed to any motive of interest, or even of his own convenience, but proceeded from his sense of duty, his real in the dissenting cause, and his attachment to his church. They prized, therefore, as they ought, the more highly; and they were proud of his growing reputation, for he was then the best preacher among the dissenters, and one of the best of those times.

The most important of Watt's publications are:—1. 'Logic,' or, the Right Use of Reason in the Inquiry after Truth: with a variety of Rules to guard against Error in the affairs of Religion and Human Life, as well as in the Sciences, published in 1725. This treatise, which appears to have been written by Dr. John Locke of Oxford, was written originally to assist the studies of Watt's pupil, Sir John Hotopp, and was revised, augmented, and published at the request of Mr. Eames. In the preface of this work, it was said: 'To its improvement, if not to the death of it, let Clerics, it must be considered that no man who undertakes merely to methodize or illustrate a system, pretends to be its author.' 2. 'The Knowledge of the Heavens and Earth made easy; or, the First Principles of Astronomy and Geography explained by the use of globes and maps, with a solution of the common problems by a plain scale and compasses as well as by the globe: written several years since, for the use of learners,' published in 1726. This is the work of an intellect untrammelled. The amount of the author's scientific qualifications may be inferred from a passage in the preface:—'Most of the authors which I have perused in these days, when I wrote many parts of this book, were of older date: and therefore the calculations and numbers which I know to be in some of these books as exact as those with which some later writers have furnished us.' 3. 'The Improvement of the Mind,' an expansion of some passages in Locke's 'Conduct of the Human Understanding.' 4. A number of works for children and of a more popular cast. These were given into the hands of the churchwardens of St. Paul's, for the support of the parson and the maintenance of the youth at school: 'Divine Songs attempted in easy language for the use of Children,' &c. It was from motives of gratitude to the provision made by Sir Thomas Abney that Watts first entered in this humbler class of compositions. No compositions of the kind have obtained such extensive use as his hymns and songs for children. Doddridge relates in one of his letters to Watts an affecting incident regarding one of them:—'I was preaching to a large assembly of plain country-people at a village, when, after a sermon from Hebrew vi. 12, we sang one of your hymns (which, if I remember right, was the 140th of the second book), and in that part of the worship I had the satisfaction to observe tears in the eyes of several of the people; after the service was over, some of them told me they were not able to hear enough of it; one old woman, so deeply were they affected, and the clerk in particular said he could hardly utter the words as he gave them out.' 5. 'An Essay towards the Encouragement of Charity Schools, particularly those which are supported by the Protestant Dissenters for teaching the Children of the poor to read, write, and perform the several branches of knowledge which Schools which instruct them to write a plain hand, and fit them for Service or for the meaner Trades and Professions of Life: to which is prefixed an Address to the Supporters of Dissenting Establishments. This pamphlet was published in 1781; a sermon which Watts had been desired to preach in the November of the preceding year, in support of the dissenters' schools. It indicates the extension of education to the poor; and the establishment of dissenting schools by the High Church party. 6. 'A Sermon preached at Berry-tree, on the occasion of the Death of our late gracious Sovereign George I., and the Peaceful Succession of his predecesor, 1829, was written at Aberdon which is chiefly valuable as an exhibition of the religious and political views of the dissenters at that period. The theological works of Watts are too numerous to admit of being recapitulated here. His 'Three Dissertations relating to Poetry and the Christian Scheme, as represented in the Psalms,' preached in the years 1718-19, published in 1781, with a preface by Dr. P. Smith, may be taken as fair specimens. They are marked by much of that logical phrase which characterizes the writer. In far as he ever craved, but far more than their average gentleness and tolerant spirit. The 'Hymn Lyric of Watts, from which an estimate of his poetical talents may be formed, was republished in 1857, with a memoir by Dr. Southey. A poet he can never be called: his works are too often turgid and sometimes nervous; and the matter is always judicious, sometimes touching, sometimes approaching to eloquence.

Watts is a classic of the people. His hymns for children have exercised an influence on the minds of the young far beyond the limits of the dissenting body. His 'Logic' was once a textbook in various places of education. He was in his day one of the most zealous advocates of the principles which placed the house of Hanover on the throne; in his pamphlet in defence of the dissenting charity-schools he was the first to enter as a text the present of German instruction who gave, at a latter time, their countenance and support to Joseph Lancaster; and his theological writings are prized by almost the whole religious public of Great Britain. If he never wrote a line in the English language is spoken Isaac Watts will be found to have exerted so important a form in the formation of public opinion. His writings have contributed much to keep alive the spirit of freedom, toleration, and piety. 'It was therefore with great propriety,' the opinion is entitled to the greater weight as coming from the high-church Tory, Dr. Johnson, that, in 1729, he was received from Edinburgh and Aberdeen an unsolicited diploma, by which he became a doctor of divinity. Academical honours would have more value if they were always bestowed with equal judgment.

The conduct of some very near relatives embittered his latter days, and for a while he seemed, being at the time in a state of extreme weakness, supplanted by it to such a degree, as hardly to take notice of anything about him. The worst of the matter was that he was not willing to Abney,' says a correspondent of Doddridge, 'keeps him in peaceful ignorance and his enemies at a becoming distance; so that in the midst of this cruel persecution he lives comfortably, and when a friend asks him how he does, answers, Well. The most invincible enemy of Watts was his fellow Dissenter, the Rev. Samuel Chandler, who wrote a funeral sermon on his text the 25th of November, 1748, and in the 75th year of his age, he departed 'in sure and certain hope.' He was buried in Bunhill Fields; Mr. Samuel Johnson paid the expenses of a funeral oration at his interment; Lady Abney and Sir John Hayton erected a handsome tomb over his grave; and the number of funerals sermons preached and published on the occasion bespoke the deep sense entertained by the dissenters of his merits. The texts of some are strikingly appropriate; that of the Reverend
David Jennings was:—By it, being dead, he yet speaketh; that of the Rev. Caleb Ashworth, "Know ye not that there is a prince and a great man fallen this day in Israel."

**WAVES AND TIDES**

in possessing many respects the same character, it has been thought proper to state in one article the phenomena and the theories of both.

From the earliest times the periodical risings and fallings of the waters on coasts or in rivers have been noticed; and the recurrences of the phenomena depend so obviously on the positions of the sun, that the inhabitants of those celestial bodies in producing them have ever been assigned as their cause. The tide appears as a general wave of water which gradually elevates itself to a certain height, then as gravitation-sinks till its surface is about as near the sea as below these causes their least to before it, and it from that time the wave again begins to rise; and this reciprocating motion of the waters continues constantly, with certain variations in the height (with respect to the mean level), and in the times of attaining the maxima of rise and depression.

Ordinary waves are produced by any cause which disturbs the equilibrium of the particles of a fluid. Thus a stone suffered to fall into water at rest gives rise to a series of concentric circular waves extending to a great distance from the point where it falls; and if a body of water from a level above that of the general surface will produce a series of waves advancing along the canal. Waves are also produced by suddenly pressing a solid into water, or by suddenly withdrawing it from the water; and such a single wave may be produced by sinning a solid body in water and moving it quickly, for a time, in a horizontal direction. The inequalities of the pressure of the air on the surface of water, whether at rest or in motion, when a gentle wind is blowing, will produce ridges, and the wind may continue long after the wind has blown a certain distance from the place of their origin, become considerable waves. In the open seas the heights of the waves depend on the force of the wind; but in confined situations both the heights and forms of the waves are affected by the resistance of the bed, by reflections from the shores, and other circumstances. When waves are formed by wind blowing from the land, each wave-surface preserves constantly the same height; but the heights go on increase, and may be seen from the shore.

Waves appear generally to be of a cycloid form: their summits have a gentle curvature, while the height bears a small proportion to the length in the direction of the motion; but as the height increases, the summit becomes more convoluted, forming a peak of a ridge, and a particle at this becomes too sharp for the preservation of equilibrium, the force of the wind acting horizontally near the top breaks it into foam or spray. As waves advance towards a shore, the water becoming less deep, the resistance of the bed increases, the heights diminish, the same time their heights to increase, so that the front of the wave becomes steep; and the motion of the upper part, towards the land, being more rapid than that of the lower part, it follows that the summit is carried beyond the point of intersection, and is supposed to be similar to a surf. The breaking of waves over a sunk shoal depends chiefly on a like cause.

The surface of the sea often presents very complex phenomena: it may happen, for example, that while a long swell is running along in one direction, a breeze will produce a series of waves moving in the direction of the wind; and a second breeze springing up in another direction will produce a new series, which will become mixed with the former without damping either, and the result may be a series of waves intersecting the other systems. When a breeze has been blowing for some time from a certain quarter, and afterwards changes to the opposite, two series of waves may be seen moving in contrary directions, and if the wind has been of equal lengths, the vertical direction of the compound wave will be equal to the sum of the difference of the ordinates of the simple waves, according as the crests are coincident, or fall in each other's intervals. These phenomena are indicated in the first and second of the subjacent figures, where ab represents the first undulation, and a'b" the second; the straight line AB being the horizontal surface of the water when at rest. Again, when there exists a third system of waves, caused, for example, by reflection from a coast, so as to be parallel to the two former systems, the combination of the three systems has been observed to produce a compound wave of the form represented in the third figure. (Report of the British Association on Waves, vol. vi.)

The waves of the sea do not extend to considerable depths: from the deep, those above, descending by appointed by the British Association in 1836, it was found that with a depth of water equal to 12 feet, waves 8 inches high and 4 or 5 feet long did not sensibly affect the water at the bottom. Waves from 30 to 40 feet long, oscillating at intervals of 6 or 8 seconds, produces some effect, but much less than near the surface; and it was ascertained that, in waves produced by the wind on the surface of a deep sea, the velocities were not a direct function of the depth.

It must not be imagined that when water is agitated by waves, its whole mass has the movement which at first sight appears from the observed progressive motion of the undulation; and, in order to account for the formation and motion of waves, it is sufficient to assume that the particles of water, when disturbed, have merely small oscillatory motions in horizontal and vertical directions. When from any cause, as the fall of a stone into it, the water becomes agitated, a series of horizontal motions to and fro are produced; and while in a slender vertical column of water the horizontal motions are in opposition, the surface neither rises nor falls; but if, in two neighbouring columns, the particles advance to meet each other, the water becoming compressed, the surface rises; if the particles retreat, the surface sinks by gravity, the surface falls. These different horizontal movements existing successively in the same vertical column, and simultaneously in those which are adjacent to each other, the surface of the water becomes undulated. In this case, however to understand the figure of waves, let the straight line ab represent the surface of water when undisturbed, and, disregarding the horizontal oscillations by which the water is alternately compressed and dilated, let the particles be conceived to ascend and descend alternately in vertical lines, that is, in lines parallel to ab or a'b", which is supposed to be particular to the place. Now, at the instant let the surface of the water have, in a vertical plane, the form abed, &c., and let the force of ascent cause the particles in the line abm to be raised up to the line a'b'm in a portion of time represented by T, that force becoming less as it is farther from horizontally, and ceasing at m; at this place the force of descent commencing, the particles in the line medn fall simultaneously with the rise of the particles in abm, and at the end of the same time T they occupy the line m'e'n. Here the force of ascent acts, and the particles in nefp at the end of the same time occupy the line nef'p, and so on. Thus at the end of the time T the surface of the water has assumed the form abf'd"e', &c. After this time the force of descent on the particles in the line of the (a'c'c') ceases to act vertically, during a time equal to T, into the line abm; at m' that force ceases, and the force of ascent raises the particles in m've'n' vertically into the line a'b'm'e'n', and so on; thus, at the end of the time 2T from the given instant, the surface of the water has the form A'B'C'D'.

Vol. XXVII. —
manner, at the end of the time \( 3T \) the forces of descent and ascent will have brought the particles into the line 
\[
a^*b^*c^*d^*, \quad \text{etc.}; \quad \text{and at the end of the time } 4T \text{ the particles will be in the line } a^*d^*, \quad \text{etc.: so that in this time }
\]
every particle of fluid has made the complete vibration vertically, as \( a^*a^*a^*a^* \), and within the same time the top of the wave has assumed successively the positions 
\[
d, \quad e^*, \quad f^*, \quad g^*, \quad A. \]
The horizontal distance from \( d \) to \( A \) is called the length of the wave; \( L \) it be represented by \( L \), and let \( r \) express the time \( 4T \) in which the summit of a wave has

\[
\text{passed from } d \text{ to } A; \quad \text{then } \frac{L}{r} \text{ is called the velocity of the wave.}
\]

On observing the characters of experimental waves in troughs with glass sides, it is found that, by the combinations of the horizontal and vertical vibrations, the particles of water describe the peripheries of circles or ellipses. In the upper parts of the curves, near the tops of the waves, the particles move with their greatest velocities in the direction in which the wave crests; and in the lower parts, near the bottoms of the waves, they are moving with their greatest velocities backwards; and at the extremities of the horizontal diameters, about the level of the preceding surface when at rest, the motion is almost wholly vertical.

The varying attraction of the sun or moon on the particles of water in the ocean is alone sufficient to produce the perturbations by which waves are formed; and if it be assumed that the solid nucleus of the earth is covered entirely with water, both on the land and on the sea, the spherical form, and consequently the long axis being in the direction of the line joining the centres of the earth and sun, and the water forming the instant of greatest

The interval between two successive culminations of the moon on the same side of the geographical meridian of any place varies from about 24 hours 40 minutes to 25 hours; and thus the intervals between the times of high-water and low-water, though of different lengths, are again and again being followed by other similar intervals of time.

The position of the moon at the time is however subject to certain variations even at the same port; and it differs considerably at different places. The elevations also of the water at the same ports, and the times of high and low water, are at a distance from one another equal to half the circumference of the earth.

Very little attention to the phenomena of the tides seems to have been paid to those in close proximity. The tides of high-water are nearly regular, the greatest elevation of the water takes place at intervals of about 12 hours 25 minutes, and the greatest depressions at the like intervals of time from each other; each greatest depression taking place at the time of two minutes, or the amount of the earth's diurnal revolution in a day; and the occurrence of high-water at any place is observed to have a dependence on the position of the moon with respect to the meridian of the place; at the poles it coincides with the moon'sApogee, and occurs every meridian, by being placed some time before or after the culmination. The position of the moon at the time is however subject to certain variations even at the same port; and it differs considerably at different places. The elevations also of the water at the same ports, and the times of high and low water, are at a distance from one another equal to half the circumference of the earth.

During about half the year, the high-tide which occurs when the moon is above the horizon is greater than that which occurs when the moon is below, and during the other half-year the phenomenon is reversed. In every place, at about the times of new and full moons, the highest tides attain their greatest elevation; and at the times of the quadratures, the least: the former are called spring-tides, and the latter neap-tides.

After the movement of the high-water coincides with that at which the current ceases to flow, but this is not the case with the sea which communicate at both extremities with the ocean. For, if it be imagined that a tide-wave flows in at one of the extremities, this will cause no motion of the current; but the waters which are passing off at the opposite extreme will, on the contrary, have a depression, or, at least, a diminution of that elevation; the surface therefore must be the highest when the current flows with equal rapidity at both extremities, and not at the time of the half-tide. When the stream continues to flow up for three hours after the high-water, it is said to make tide and half-tide; if it continues to flow during one hour and a half, it is said to make tide and quarter-tide, and so on. Near the shores of the British Channel, probably in consequence of the obstructions caused by the land, or the disturbances at the mouths of rivers, the progressive movement of the tide-wave is more retarded than in the middle; and in some places the current has curvilinear motions, which on the French coast are on the sides and in opposite directions. The race of Portland is a current produced by the tide-wave, while advancing along the shore; being arrested by the promontory till it attains a height which allows it to flow off obliquely at a considerable velocity.

The race of a tide-wave near the top of the wave places rapidly the shoving of the sea and the confinement of the water between the banks; for the motion of a body of water is capable of raising the particles to the height through which they have actually moved, and which is calculated from the wave; and if the same motion is employed in raising a smaller quantity of water, it is evidently capable of raising it higher; thus, when the contraction is considerable, as in the Bay of Fundy, the Bristol Channel, and other places, the elevation becomes very considerable; at Cheshw. it amounts to 60 feet. When, at the mouth of a river, the bed has a long and gentle slope on each side, the waves, becoming high and steep, fall river, and flow up rapidly with a surf, constituting what is called a bore; the Dee in Cheshire, where it enters the English sea, which occurs in the Amazon is said to be from 12 to 15 feet in height. In flowing up a river the summit of the tide-wave reaches the different stations later as these are further from the mouth; and in the Tames it advances half a day, a month, and a year in the years of highest tides.

It is observed also that the current of a river runs upward during some time after the summit has passed any station, and downwards for some time after the surface of the water is at the lowest; the intervals between the times of passing the other stations are greatly diminished as the stations are further apart, while the intervals between high and low water increase.

From the observations made by the committee of the British Association in 1830, on the tide-waves of the river Dee at Cheshire, it was found that the average time of advance of the tide advanced 5'275 miles in intervals of time varying from forty-five minutes to one hour, or, at an average, at the rate of 6'4 miles per hour; and that the wave of high-water advanced the same distance with a velocity, by an average of 10'0 miles per hour, which, it is said however to have been impossible to determine whether the wave which carried the flood-tide to the lower station was the same as that which carried it to the higher. It is thought probable that the wave which passed the mouth of the Dee would have been very much faster than that which has its origin in the mouth of the Thames. The current in the Dee is represented by a subsequent wave from the sea. The wave of high-water, being above those obstructions, flowed up more regularly, and the observed height of the wave has been estimated with near certainty from the measure of the wave's observed velocity: it being understood that the velocity of a wave is that which would be produced by a body falling from rest through half the height of the wave.

In order that the phenomena of the tides at different places may be readily compared together, charts have been constructed, on which are drawn curve-lines joining the points at which high-water takes place at the same time. Now, the heights of the wave and the times of its greatest elevation vary at every place from day to day, it is clear that the necessity of knowing the time of high-water, the number of hours it advanced, and the times of the quadratures; and on this account, by general agreement, the time of high-water at every seaport on the days of full and change of the moon is chosen. This is called the Establishment of the Port, and an extensive table of Establishments for the ports of Great Britain and Ireland is given in the 'Nautical Almanacs,' the hours and minutes indicating the time from apparent noon on the days of new and full moon when high-water takes place. Since, on the first of these days, the moon passes the meridian of the port, the time of the elevation of the high-water may be found from the table by merely adding the Establishment to the time at which the moon comes on the meridian on the given day. Finding upon the surface of the earth and sea any number of points at which the Establishment is reckoned, it is known that there is the same, a line drawn through all the points will indicate the summit of a great tide-wave at that time: drawing a curve in like manner through all the points at which the Establishment in Greenwich time is an hour later.
there is obtained a new position of the summit; and it must then be understood that the wave has travelled, in the sense above explained, from the first line to the text in one hour. These are called 'Cotidal lines;' they were first indicated on a chart of the world by Mr. (Sir John) Lubbock, in the 'Philosophical Transactions' for 1831, and an extensive series of such lines are traced on the chart which accompanies Mr. Whewell's 'Essay towards an approximation to a Map of Cotidal Lines,' in the 'Philosophical Transactions' for 1833.

The definition above given of the 'Establishment' is only approximately true: it is observed by Mr. Whewell, in the 'Essay,' that it would be correct if the high-tide always occurred when the moon's hour-circle makes equal angles with the meridian; but in fact the hour of tide on any day is reckoned from the time that the sun is on the meridian; and as the moon changes her right ascension every day by about forty-eight minutes (the observed hour of the tide being given on the day of new or full moon), the moon's hour-angle may differ according to the time of the day when the conjunction or opposition takes place, compared with the time of day when the high-tide is observed. Therefore an observation of the hour of the tide on the day of new or full moon may leave an uncertainty of about 1h. 8m. in the time of the 'Establishment,' unless account is taken whether the morning or afternoon tide was observed, and at what hour the straggy took place.

The subjoined cut, which shows the principal cotidal lines in the Indian and Atlantic oceans, is from Mr. Whewell's chart above mentioned, and contains the modifications introduced in that which is given by Mr. Airy, in his Essay on 'Tides and Waves,' in the 'Encyclopaedia Metropolitana.'

In investigations relating to the tides, it is required to determine the form assumed by the surface of the water when the particles are subject to the actions of disturbing forces; and for this purpose it is convenient to assume that if no such forces existed, the earth would consist of a solid spherical nucleus within a body of water whose external surface is that of a sphere concentric with the nucleus. Let the circle \( cd \) represent the nucleus, and the circumference \( ab \) the surface of the surrounding water in a plane passing through the centre of the earth, and the sun or moon at \( M \); then, in the theory indicated by Newton, the attraction of the celestial body will draw the particles of water towards it so that the surface \( ab \) will assume the form \( a'b' \); at the same time the attraction exercised on the solid part \( cd \) will cause the latter to take the position \( c'd' \). Thus at the same instant the surface of the water at \( a' \) and \( b' \) is farther removed from the centre of the earth than it would be if there were no perturbation; while at \( e \) and \( \delta \) it is nearer. If the central body were constantly in the plane of the equator, the summit of the elevated water would also be in that plane, and exactly or nearly under the body. A section of the spheroid of water passing through the poles of the equator and the summit just mentioned would be an ellipse, and its periphery would coincide with the direction of a terrestrial meridian.

By the diurnal rotation this tide-wave, as it may be called, would appear to move about the earth from east to west at the rate of above 1000 miles per hour at the equator; and its positions at the rate of every 1 hour would constitute a series of cotidal lines. Hence, if a small island at the terrestrial equator were to project above the surface of the water, it would arrive successively at the points \( a', e, b', f, \alpha' \), so that in the time of a rotation of the earth on its axis with respect to the celestial body, there would be at the island two states of high-water and two of low-water.

The arrival of the island at the summit \( a' \), which would, if \( M \) were the moon, take place at the end of every 24h. 50m. nearly, is called the diurnal tide; and that which takes place when the island arrives at the summit \( M \), that is at 12h. 25m. after the former, is called the semidiurnal tide. By this theory there ought to be scarcely any tides near the poles, the water being always drawn from them towards the tropical regions; and the attractions of \( \epsilon \) under the celestial body, where the moon's distance is equal to two, it should follow that the diurnal tide is greater than the semidiurnal tide, neither of which circumstances is conformable to observation.

If an island having a great extent from the equator towards the north and south were to intercept the tide-wave, the elevated water, passing round the extremities of the island, would on its western side form two waves, which would advance towards, and meet one another at the equator, making, at different places on the coast, high-water successively later, in the directions of their motion. And it is easy to conceive that the tide-wave of a great ocean will send branches into any seas which it may approach in its movement about the earth: such are called derived tides.

The combined actions of the sun and moon, when those luminaries are in conjunction or opposition, that is, at new or full moon, may be readily conceived to produce what are called spring-tides; and the diminution of each other's attractions when in quadrature, to produce the ebb-tides. It may further be understood that, as the distances of the sun and moon from the earth vary by the ellipticity of the orbits; at the times when either of the celestial bodies is in perigee, its attractive power being greater than at other times, the tide-wave raised by it will attain a greater elevation than usual; on the other hand, when in apogee, the high-water elevation must be the least.

The tides are greatly modified at any station or port by the position of the latter with respect to the equator, and by the declination of the central body of the tide-wave are, at the same instant, diametrically opposite to one another; and if the latitude of the station were equal to the moon's declination on a given day, both moon and station being for example north of the equator, the summit of the wave would on that day be at the place where the moon is in or near the zenith, but about twelve hours afterwards, the station, having described half the circumference of a circle about the earth's axis by the diurnal rotation, will be on the opposite side of the meridian of the equator; and the summit of the wave on the other side of the equator, will be at a distance from the station equal to twice the moon's declination; consequently the height of this tide will be much less than that of the former tide. The contrary phenomenon occurs when the moon and the station are on opposite sides of the equator.

The only tides with which we can be said to be well acquainted are those of the Indian and Atlantic oceans; and from the known times of high-water at different places, it is ascertained that the summit of a wave advanced from the equator to the north, to the south of New Holland into the Bay of Bengal, and towards the Persian Gulf, causing the hour of high-water to be successively later at the ports from Ceylon northwards, on both sides of the western peninsula of India. The summit of a single wave may extend from the mouth of the Red Sea, along the eastern
coast of Africa, to the Cape of Good Hope, where it joins the tide-waves of the Atlantic. These advancing northwards, cause the time of high-water to be successively later at the different ports on the western coast of Africa and Europe, 17° land on the whole coast of South and North America; so that the wave which at a certain instant is at the Cape, in 16 hours from that time is at the mouth of the English Channel and on the western coast of Ireland. This wave, being apparently checked in its progress by the British Islands, is divided into two principal branches, of which one flows up the Channel, and passing through the Straits of Dover, is off the mouth of the Thames in 8 hours from the time that it was at Brest. A small branch advances up St. George's Channel; but the second principal branch of the wave flowing round the southern extremity of Scotland, proceeds slowly down the North Sea, and meets the first branch off the mouth of the Thames in 20 hours from the time that it was at the entrance of the Channel.

From Rio Janeiro to the Falkland Islands a wave summit seems to advance directly from east to west; and from the form of the continent of South America, the high tide occurs successively later in going southward from Cape Frio, as if the wave came from the east. The waves from the north also flow northward, from Terra del Fuego and the Falkland Islands to the coast of Patagonia, and at Port St. Elena on that coast it occurs 12 hours later than at those islands. On the western coast of America the tide seems to flow to south, being repelled by the Straits of Magellan; while from the former place it travels northwards. In the Pacific Ocean the general direction of the tide-wave is from east to west; but the heights of the tides are small, not exceeding 2 feet at the islands of the South and South Atlantic, by Mr. W. M. Johnson ('Phil. Trans.,' 1833) that this must not be understood to be the tide which would be raised if the whole earth were covered with water, on account of the modifications produced by the form of the continent of South America. The mouth of the San Francisco Bay, 37° and 30° S. lat., has the high-tide earlier than points which are situated towards the north or south of that tract.

Peculiarities in tides, arising from the interference of waves, occur in many different places. In the middle of the North Sea there is supposed to be a considerable space within which the tide produced by the waves coming from the north and south takes place at one time. And Mr. Whewell states, on the authority of Captain Hewett, that about the Orver Shal there is no sensible rise of the tide till 3 hours after the time of low-water; but when the ebb stream has nearly ceased, there is a sudden rise of 5 or 6 feet; so that nearly the whole rise of the tide occurs in the last 3 hours.

In 1740 the Académie des Sciences offered a prize for the best memoir on the theory of tides; and the paper by Daniel Bernoulli on the flux and reflux of the sea shared it with those of Euler and Maclaurin. In that paper it is assumed that the water is kept in equilibrio by the attractions of its particles towards the earth's centre of gravity and the disturbing forces exercised by the sun and moon; and though the results of that theory are found to differ greatly from the observed phenomena, the theory itself is deserving of attention, since the analytical expressions which have been obtained by it first exhibited a few phenomena distinctly from one another: those expressions consequently became guides to the observer or experimenter in his efforts to ascertain the true values of the Earth's forces, on the representation of which they are founded.

Though the attraction exercised by the solid nucleus of the earth on a particle of water at any distance from its centre, being considered the same as it would be if all the matter of the nucleus existed in that centre, is represented by \( E \), \( E \) being the mass of the earth and \( r \) the square of the distance of a particle from the centre. But if \( x \), \( y \), and \( z \) are rectangular coordinates of a particle, the centre of the earth being the origin, we have \( r = x^2 + y^2 + z^2 \); and the partial differentials of the expression \( E \), relatively to \( x \), \( y \), and \( z \), represent the effects of that attraction upon a particle in the directions of the three axes. If the attractions on the particles of water for each other are taken into consideration, there must be determined the attraction exercised upon a particle by all the water between the spherical nucleus and the exterior surface (supposed to be spheroidal) of the surrounding fluid, and the expression for this attraction must be added to that for the solid.

The disturbing forces on the sun or moon upon a particle of water is represented by \( F \); \( S \) being the mass of the celestial body and \( R \) the distance of the particle of water from it; and the partial differentials of that expression relatively to \( x \), \( y \), and \( z \) give the values of the attraction in the directions of the coordinate axes: but the disturbing force exercised by the sun or moon on a particle of water being equal to the difference between its attraction on the particle and its attraction on the centre of the earth—the latter, which is represented by \( D \) (being supposed to be the distance between the centres of the earth and celestial body), is subtracted from the attraction exercised on the earth and the sun, and the result thus obtained from the sun, and the result thus obtained is supposed to be parallel to the line joining those centres, in order to have that difference. The attracting forces of the earth in the directions of the three axes being subtracted from the disturbing forces of the sun or moon in the same directions, the remaining force is represented by \( X \), \( Y \), and \( Z \) by Mr. W. M. Johnson ('Phil. Trans.,' 1833), and by Mr. W. M. Johnson ('Phil. Trans.,' 1833), and is an exact differential; the form of the expression for the equilibrium is determined by making the integral of the expression constant.

The resulting equation being found to correspond with the general equation to a spheroid, a comparison of like terms in the two equations gives the values of the constants which enter into the former. If \( r \) represent the mean distance of the spheroidal surface of the water from the centre of the earth, and \( \alpha \) represent the distance of any point on that surface above or below the mean level; then \( r + \alpha = \rho = \rho_A \) is the radius of the surface, and the determination of \( \alpha \) for any place gives at that place the height of the water above, or its depression below the mean level.

Uniting the effects of the solar and lunar disturbances by simply adding them together, since the disturbing forces are very small compared with the force of gravity; and introducing, in place of the rectangular coordinates, angles which depend on the longitude and latitude of a station, with the right ascension and declination of the sun and moon, to be very small, the value of the equations consist of three parts: one of these depends on the variation of the declination of the sun and moon, and indicates a slow tide which goes through its changes in about fourteen days; the second depends on the hour angles both of the sun and moon, and indicates a slow tide through their changes in a solar and a lunar day respectively. These being combined, there is produced a diurnal tide, the highest state of which should precede, at a variable interval, the moon's culmination between the times of rising and setting of the sun, and should follow it between the quadratures and syzygies. It has been found however that the observed accelerations and retardations, and also the absolute elevations of the water, in very few cases agree with the results of the theory.

The third part depends on the hour angles just mentioned, and consequently indicates two semi-diurnal tides, which being combined constitute one such tide, whose highest state is variable. The nature of the expression shows that the diurnal should be the greatest at the equator, and should diminish till it vanishes at the poles: it denotes also that it is greatest at new or full moon, and least at the quadratures. The theory moreover indicates that the difference between two consecutive times of high water ought to keep the same distance from one another, whereas they are known to be nearly equal to one another. Both Newton and Bernoulli endeavoured to explain this circumstance by the hypothesis of a general oscillation of the sea, in consequence of which the highest tide gives to the lowest a quantity equal to the difference between them; but the researches of La Place have shown that, even with such oscillations, the two tides could not (according to the theory) be equal unless the sea were everywhere equally deep.

Euler, departing from the hypothesis that the sea is
always in equilibrio under the action of the sun and moon, endeavoured to introduce the subject of fluid oscillations in his theory of the tides; but the laws of undulations were not then known, and Euler assumed that a molecule of the sea in motion endeavours to regain the position which, in a state of equilibrium, it would occupy in a vertical line with a force proportional to its vertical distance from that position.

The theory adopted by La Place, in which there are taken into consideration the laws of fluid molecules when acted on by attracting forces, was a great improvement on that of the mathematicians before mentioned; and it is found to produce a more near agreement with the observed phenomena. The elaborate investigations of La Place will be found in the Mémóires de l'Académie des Sciences for the years 1775, 1776; and in the first and fourth books of the Mécanique Céleste. As in the former theory, the solid nucleus of the earth is supposed to be entirely covered with water of uniform depth, and the investigations commence with the proof (Méth. Ed, liv., i., ch. 8) that any portion of the water, however its place may be changed, will always retain the same volume. The equation expressing this law is called the equation of continuity.

A very small parallelepiped of water within which covers the solid nucleus of the earth is acted upon by accelerative forces arising from pressures estimated in the directions of three rectangular coordinate axes whose origin is at the centre of the earth: the first is supposed to be parallel to the axis of rotation, and the others in the equator plane of the equator, one being directed to the equinoctial point and the other at right angles to that direction. The pressures are supposed to arise from the attraction of the earth, from the angular velocity of its rotation, and from the disturbing forces, and to tend towards the origin of the coordinates.

These pressures, which are expressed by partial differential coefficients relatively to $x$, $y$, and $z$, in the coordinate axes, are subtracted from the accelerative forces arising from the attraction of the earth, and the perturbations exercised by the sun or moon, by which the molecule would be made to recede from that origin; and the differences in the directions of the axes are represented by

$$d\tau = \frac{dy}{dt}, \quad d\sigma = \frac{dz}{dt}, \quad \text{and} \quad d\psi = \frac{dx}{dt}.$$ 

In these equations of motion the partial differential coefficients representing the pressures are transformed into others depending on the distance of the molecule from the centre of the earth, and on its latitude and longitude; while the perturbations of the sun or moon in the directions of the coordinate axes are expressed in terms of the right ascension and declination of the disturbing body, and also of the distances of the latter from the particle disturbing the earth. The first result is that the expression for the altitude of a molecule of water above the mean level, in consequence of the perturbation produced by the sun or moon, consists of three parts (Méth. Ed, lib. iv., c. 1); the first does not depend on the rotation of the earth, and indicates a tide which goes through its changes in a long period; it may consequently be disregarded. The second depends on that rotation and on the hour angle of the disturbing body: it indicates the diurnal tides, or those which take place when the celestial bodies are on or near the meridian, above the horizon, and which follow one another at intervals of twenty-four hours for the sun, and about 24h. 50m. for the moon. The third depends on an angle equal to the double of that on which the second depends; and consequently it represents the semi-diurnal tide.

But the subject of waves and tides has been treated in conformity to the theory of undulations by Mr. Airy, the astronomer royal, in a valuable essay which is published in the Encyclopaedia Metropolitana. The investigations, though admitting of general application, are particularly adapted to the phenomena of tides in rivers and arms of the sea; and they are conducted by an analysis within the reach of persons acquainted with the ordinary processes of the calculus of finite differences.

As in the theory of La Place, there is formed an equation of continuity, which is founded on the equality of a rectangular parallelopiped of water at rest, to the oblique parallelopiped formed, when the water is in a state of disturbance, by the new positions of the eight particles constituting the angular points of the former parallelopiped. But, as the water is supposed to be in a rectangular canal, the extent of the parallelopiped in the direction of the breadth of the canal is supposed to be constant; and therefore it is sufficient to assume the equality of the parallelograms which form a side of each in the direction of the length of the canal.

The canal being of uniform depth, the equation of continuity is expressed by

$$Y = \int dX \frac{\partial}{\partial x}$$

where $x$ and $y$ are respectively the horizontal and vertical coordinates of a particle of fluid, and where $X$ and $Y$ are respectively the horizontal and vertical displacements of the particle by the action of the disturbing forces: the equation expresses a relation between those coordinates and the disturbances or displacements.

An equation of the pressure experienced by any particle from the forces which act upon it is next found in the following manner. Let $p$ represent the pressure in every direction on the lower part of a disturbed molecule of water in consequence of the height or weight of the filament of particles above it: then, the vertical coordinate of the particle being $y'$ or $y + y'$, suppose in the element $dt$ of time the vertical coordinate to become $y' - by'$ (the vertical height of the filament above the molecule in that direction being increased by the general revolution of the earth). Then, the pressure on the upper part of the molecule will be greater than before, and may be represented by $p + \frac{dp}{dy'} y'$; consequently the molecule may be supposed to be pressed downwards by a force represented by $\frac{dp}{dy'} y'$. Now, in order to render the expression for the hydrostatical pressure homologous to that which is employed for the force of gravity, it must be considered as accelerative, or as a motive-power divided by the mass; and therefore the accelerative pressure downwards becomes $\frac{dp}{dy'} y'$ being added to $g$, representing the force of gravity and supposed to be constant, there arises $\frac{dp}{dy'} y' + g$ for the whole acceleration of the molecule downwards; hence there is obtained the equation

$$-\frac{dp}{dy'} = \frac{dy}{dy'} + g.'$$

The equation, being integrated between the limits for the bottom of the basin and the top of the water, gives the hydrostatical force by which a vertical filament of water descends, or that by which it is carried forward horizontally.

Let the slender column of water above the molecule have a horizontal breadth equal to $h$ in the direction of $x$; then the horizontal pressure in front, by which the column is forced backwards, will exceed the pressure by which it is carried forwards by a force represented by $\frac{dp}{dx} h$, or by an acceleration represented by $\frac{dp}{dx}$; therefore the horizontal acceleration forwards is $-\frac{dp}{dx}$; if extraneous forces, as the attraction of the sun or moon on the molecule, and the effects of friction, be together represented by $F$, when estimated in the direction of $x$, there arises the expression

$$F - \frac{dp}{dx}$$

for the whole acceleration forwards; then the equation of motion becomes

$$d\tau = \frac{F - \frac{dp}{dx}}{dt}$$

which gives relations between the terms $X, Y, x, y,$ and $t$. This equation of equal pressure and the equation of continuity constitute the theory of the motion of fluids in case of uniform horizontal motion.

The general equation representing the disturbance or displacement of a particle of water is the same as that which expresses the disturbance of a particle of light.

A W V

the 'undulatory theory'; and, in order to indicate oscillatory motion, both the horizontal and vertical displacements are represented by terms containing the sines or cosines of angles depending on the time \( t \).

If it be assumed that

\[ X = R \cos (nt - mx) + S \sin (nt - mx), \]

\( R \) and \( S \) being functions of \( y \), the above equations of continuity and of equal pressure give, on the supposition that gravity is constant, that no extraneous forces act, \( Y \),

and retaining for the present only the first power of \( \frac{dX}{dt} \), or of the horizontal displacement,

\[ \frac{d^2 X}{dy^2} + \frac{d^2 X}{dx^2} = 0. \]

From these two equations are obtained the values of \( X \) and \( Y \) in terms of \( A \cos (nt - mx) \) and \( B \sin (nt - mx) \).

These values will not be altered if \( mx \) is increased or diminished by one, two, three, &c., whole circumferences,

that is, if \( x \) is increased or diminished by \( \frac{2\pi}{m} \), &c.,

while \( t \) remains the same; therefore \( \frac{2\pi}{m} \) is the value of the increments of \( x \) which correspond to points where the particles of water are in the same condition with respect to disturbance, that is, \( \frac{2\pi}{m} \) is the length of a wave. Again, the values will not be altered if \( nt \) is increased or diminished by whole circumferences, that is, if \( t \) is increased or diminished by \( \frac{2\pi}{n} \), &c., while \( x \) remains the same;

therefore \( \frac{2\pi}{n} \) is the increment of time which corresponds to the particles of water being successively in the like state of disturbance, that is, \( \frac{2\pi}{n} \) is the period of a wave, or the time between two successive formations of a wave-summit at the same place. Therefore \( \frac{2\pi}{n} \) is the velocity of the wave; and, from the value found for it by the theory, it follows that the velocity depends on \( m \) and on the depth of the water; the latter being constant, the velocity depends on the length of the wave, or it depends on the time in which a particle of water makes a complete vibration. If the wave is divided or the time of its vibration is given, the velocity will vary with the depth of the water.

From a table of the computed velocities of waves of different lengths, and with different depths of water, it is found that when the length of the wave is not greater than the depth of the water, the velocity of the wave is proportional to the square root of its length: also when the length is not less than one thousand times the depth of water, the velocity is proportional to the square root of the depth, and is the same as that which a body would acquire in falling from rest through a height equal to half that depth. The greatest horizontal and vertical displacements of a particle being computed for different values of the length of the wave and the depth of the water, it appears that when the latter is great, compared with the former, as in the open sea, the motion of the water below the surface is very small compared with the motion at the surface; and at a depth equal to the length of wave, it is only about \( \frac{1}{6} \) of the motion at the surface. On the same supposition the greatest horizontal motion is equal to the greatest vertical motion. When the length of the wave is great compared with the depth of the water, as in tide-waves, the horizontal motion of the particles is nearly the same from the surface to the bottom, and the vertical motion varies from a maximum at the surface to a minimum at the bottom. On the same supposition the vertical motion of the superior particles is much less than their horizontal motion.

The movement of a particle of water near the surface may be determined from the values given by the theory to \( X \) and \( Y \): if the waves are small, so that \( A \) and \( B \) may be considered as equal to \( B \), we have \( (X^2 + Y^2)^{\frac{3}{2}} = C \), a constant; which, being the equation of a circle, it follows that the particles move in the circumference of a circle whose radius is \( A \); but if the length of the wave is great compared with the depth of water, the equation is that of an ellipse. These last deductions from the theory are conformable to what has been observed in experimental waves, as above mentioned. It follows that, in a long tide-wave flowing up a channel, the direction of the wave's motion is the greatest at the summit of the wave, that is, at high-water: at the place of greatest depression, that is, at low-water, the motion is most rapid downwards; and at the mean level the water is for a time stationary.

In investigating theoretically the phenomena of waves by whatever cause produced, if the lengths of the waves are very great compared with the depth of the canal in which they move, it becomes necessary to retain the second and even higher powers of \( \frac{dX}{dt} \) or of the horizontal displacement, in the equations of continuity and of equal pressure; but the vertical oscillations being then small, the value of \( \frac{dY}{dt} \) may be neglected. Then, if the perturbing actions of the sun and moon are not considered, the integration of the differential equation of equal pressure gives a new form of the vertical displacement at any point, or the height of the wave above the mean elevation, in terms which contain \( k \), \( \sin (nt - mx) \) and \( kx \sin (2nt - 2mx) \), \( k \) being the depth of water in the canal.

Tracing an undulating line whose ordinates are the values of the greatest wave-length, corresponding to the horizontal distance \( X \), the horizontal distance from the mouth of the canal, which is supposed to open to the sea; it is found that, near the opening, the front and rear slopes of the waves are of equal lengths and of similar forms: but as the distance from the sea becomes greater, the front slope is shorter and steeper, and the rear slope longer and more gentle: at a great distance the latter becomes nearly horizontal in the middle, and at length it divides into two gults, so that the wave becomes double. Near the sea also, the time occupied by the passage of the wave is as the time occupied by its descent: at a certain distance the rise takes place in less time than the descent; and at a still greater distance the descent, after having been rapid, is checked, and changed into a rise, to which another rapid descent succeeds; so that there seem to be two tides, or elevations of the water, in the upper part of the canal, corresponding to one elevation at the mouth.

The value of \( \frac{dX}{dt} \), or the velocity of the particles of water, is found also to contain the sines and cosines of the angles above mentioned; and, substituting in these the greatest wave-length and the greatest wave-elevation, it is found that the velocity corresponding to the first of these values, that is, at the top of the wave, is less than the velocity corresponding to the other: but the former, the first case, is up the canal, and in the other case down it; and these are nearly the same as the greatest velocities of the water; consequently the velocity of the flow of the wave in the canal is less than that of the ebb. The preceding conclusions relate to the case in which the water was at rest in the canal previously to the formation of the wave: in the event of the water having a general movement towards the sea, the time in which the wave rises, or the time from low-water to high-water, is still less than the time of the descent; but the difference between the two is two-thirds of that of which the waves would have in a rectangular bed of equal breadth and depth.

When water, still supposed to be in a canal of uniform breadth and depth, is disturbed by extraneous causes, as the attraction of the sun or moon, the term \( f \) in the equation of equal pressure is conceived to consist of two, one represented by \( H \) sin. \((nt - mx)\) for the horizontal inertia of a much force in the direction of \( x \), and the other by \( G \cos. (nt - mx) \) for the vertical intensity; and the equation for \( \frac{dX}{dt} \) being then satisfied by the equation \( X = g \cdot f \cdot y \) sin.
\[ (t - \mu z), \text{ in which } \phi'(y) \text{ represents the second differential coefficient of a function of } y \text{, there is obtained a value of } X \text{ at the surface of the fluid in terms of } \sin \left(\frac{t - \mu z}{2}\right), \text{ and } 2 \cos \left(\frac{t - \mu z}{2}\right). \]

The wave thus indicated depends upon the continuity of the actions of the extraneous disturbing forces, and is designated by Mr. Airy the forced-tide wave. This wave, he observes, would cease to exist if those forces were to cease, and in such a case the free tides would continue as before.

Tides, Taking into account the effects of friction, which may be considered as a horizontal retarding force proportional to the velocity, and which may consequently be represented by \( -\frac{dX}{dt} \); the value of \( X \) contains terms involving the sines and cosines of angles represented by \( t - \mu z \) and \( t \pm \phi z \), and the expression for the vertical elevation contains the sine and cosine of \( t - \mu z \). The analytical expression remaining from the production of this additional perturbation indicates the fact that the disturbance of the water takes place later than the times at which the disturbing forces arising from the action of the sun or moon are the greatest; and this circumstance gives to the wave theory an improvement over those of Newton and Laplace; for in both these theories the greatest tides take place when the force is the greatest.

In the case of a canal bounded at both extremities, the expression for \( X \), the horizontal disturbance of a particle, is found to be the sum of two parts: one of which is the horizontal motion due to the motion of the particle of water, the combination of free tide-waves, probably caused by ex-1

The theory of which a brief outline has just been stated, applies to what are called negative waves by a mere change of the sign of the expressions of the disturbing factors. These waves are depressions below the general surface of the water, and, like the others, they have a progressive motion. Such waves, for example, are those which are formed by the paddles of a steam-boat.

All the theories concur in showing that the difference between the diurnal and semidiurnal tides is great in middle latitudes, and small at the equator and poles; and in this respect they are at variance with the actual phenomena. From observations it is found that this difference is as great at certain places near the equator as near the latitude of either tropic: it has also been found to be great at Petropawlowski and in Norfolk Sound, while in Europe it is small. It has been attempted to account for the latter circumstance by assuming that each tide-wave in this part of the world is composed of two, which flow towards the same place in opposite directions at intervals of about twelve hours. It is supposed that the semidiurnal waves of these tides, being in the same state or phase, produce together a tide whose diurnal wave is in opposite states; so that the superior high tide of one wave coinciding with the inferior high tide of the other, they together produce a mean height of water differing but little from that of the united semidiurnal tides.

For the details of the investigations relating to the theories of the oscillations of water, discussions of the experiments which have been made by Mr. Russell and others on waves in artificial canals, methods of making observations on tides, and accounts of the particular tides of various seas and rivers, see the above-cited work 'Tides and Waves, in the Encyclopaedia Metropolitana.'

**WAVELLITE.** Hydargillite, Devonite, Lasonite. This mineral, which is a phosphate of alumina, was discovered by Dr. Wavel, whence its name. Occurs in globular concretions from a very small size to that of an inch in diameter; these consist of small slender crystals radiating from a centre, with imperfect terminations. Primary form of the crystal a right rhomboide prism. Cleavage parallel to the lateral planes, and the greater diagonal of the prism. Hardness, 3.5 to 4.5. It is of a soft texture and is nearly white; grey, brown, yellow, and green of various shades. Lustre vitreous, somewhat pearly on the cleavage planes. Transparent, translucent. Specific gravity, 2.3 to 2.5.

Before the blow-pipe, it swells and becomes snow-white; when powdered, it dissolves without effervescence in nitric and sulphuric acids when heated, and gives out an acid which slightly corrodies glass.

This mineral is found at Barnstaple, Devonshire; near Cork, Ireland; in Cornwall, Germany, Brazil, &c.

**Analysis of the mineral from Barnstaple,** by (1) Fuchs, (2) Berzelius:—

**WAVENY. [NORFOLK.]**

**WAX.** There are many varieties of this substance, but the term used by itself means bees'-wax. This wax is the product of the bee's pollen elaborated by the bee; but it is now admitted to be a secretion from its ventral scales. With this substance the comb is constructed, the cells of which are hexagonal; from the comb the wax is extracted chiefly by pressure, then melting it in hot water, by which the impurities subside, and the wax is poured into and allowed to cool in moulds.

The properties of wax, or rather of yellow wax, are— that it has a yellowish or orange colour; its odour is peculiar. Even in winter it is soft enough to be indented by the nail, and in summer it is much softer. Its density varies from 0.960 to 0.965. It melts at about 143° to 150° Fahir. It is a nonconductor of electricity.

White or Bleached Bees-Wax is obtained, as stated by Dr. Pereira (Mort. Med., p. 1391), by melting yellow wax by means of steam, running it off, while in a melted state, into a trough called a cradle, perforated at the bottom with holes, and placed over a large water tank, at one end of which is a revolving mill, almost wholly immersed in water. By this means the wax is solidified, converted into a kind of ribbon, and conveyed on the surface of the water to the other end of the tank. These ribbons of wax are here lifted out and conveyed in baskets to the bleaching grounds, where they are exposed to the air for one or two weeks (according to the state of the weather), being turned every day. The wax is then remelted, re-ribboned, and re-bleached; it is subsequently refined by melting in water acidiudated with sulphuric acid.

Pure wax thus obtained is nearly devoid of smell.
WAX

152

When wax is strongly heated it is decomposed, yielding the usual products of non-saturated vegetable matter. According to Hess, when wax has been deprived of its colouring matter by ether, white scales of wax are procured, which yield by analysis:

Wax is extensively employed both in its original and bleached state; in the latter it is used not only for candles, but also in numerous cerases, ointments, and plasters.

Myrtle Wax is a vegetable product, obtained from the berries of the Myrica cerifera, a native of the United States of America. It is a soft, mobile, brownish mass, in pieces of various sizes and shapes; it is non-saponifiable fat, and the wax, when boiled in water, is skimmed off, and re-melted. It is greenish, diaphanous, and bleaches perfectly in the sun; it is so brittle that it may be pulverized. Its density is 1; it melts at about 69 Fahr., and yields wax products; thus, the wax-palm of the Andes (Cercozyon Andicola) is a tree which grows to the height of 190 to 180 feet, and yields a mixture of wax and resin, of which the natives make candles. From the resin Bonastre has extracted a substance which he calls cereozine. Another variety is produced by the Wax-Tree.

WAX-TREE, the common name of the plants belonging to the genus *Vermes*. This genus was named in honor of a merchant, a merchant of France, and belongs to the natural order Hypericaceae. It has a 5-parted calyx, with five petals villous inside, a membranaceous berry, five styles with peltate stigmas, numerous stamens disposed in five bundles, which are placed opposite the petals, and alternate with these the name of the androecium is roundish, 2-celled, and branching lengthwise; seeds with a double covering. The species are either shrubs or trees, having quadrangular opposite branches with entire leaves full of glundular and pellucid dots. The flowers are of a yellow or greenish colour. All the species afford a yellow juice, which is sometimes collected and sold in the markets under the name of American Gamboge. All the known species, except one, which grows in Africa, are natives of various parts of South America. The species in greatest request are the following:

*Vermes guianensis*, Guiana Wax-tree, has a quadrangular stem, ovato-lanceolate or oblong leaves, which are dilated at the base and fleshy and smooth beneath; the petiole is short, the calyxes ovate, the stamens ciliated, the stamens numerous, and the berry ovate. This plant is a native of Guiana and Brazil. It is a shrub about eight feet in height. The Cayenne Wax-tree (*V. cayennensis*) has dotted ovato-lanceolate leaves, and few-flowered panicles of flowers. It attains a height of about ten feet, and all parts of the plant yield the resinous juice.

*V. setifera*, has an angular stem, lanceolate leaves, coriaceous at their base, with very short and thick petioles, and a multifid pulvinule. It is a native of Guiana, and yields the juice in great abundance. *V. ladifolia*, with broad dotted leaves and dotted petals, is another species of Guiana, which yields great quantities of the juice when cut or broken. The juice when dried is purgative in doses of about seven or eight grains.

**WAX SEALING.** The best red sealing-wax is composed of shell-lac, Venice turpentine, and cinnabar. The shell-lac by itself is rather too brittle, and the turpentine is added to remedy that defect. The proportions are about four parts of lace, one part of turpentine, and three parts of cinnabar, by weight. When the lace and turpentine are well stirred in the proper proportion, and the whole well mixed by stirring it about. The round sticks of sealing-wax are made by hand on a smooth slab of marble or plate of metal, which is kept at an even and moderate temperature by a Brazier or chafing-dish placed beneath it. The liquid sealing-wax having been partially /cooled, a quantity sufficient to make about six sticks is rolled out on the slab or plate into one long stick, which, when of proper diameter, is cut into lengths, and transferred to the sealing-maker, who rolls it over a cold slab beneath a smooth piece of wood or metal. The sticks are now to be polished, which is done by holding them successively between two contiguous charcoal fires till the surface is fused, which produces the polish. One end is then softened by being brought near the flame of a lamp, in order to receive the impression of the maker's name. This manipulating process is only applied to the round sticks; those which are oval and ornamented are formed by pouring the liquid sealing-wax in molten wax into a mould, and while partly cooled, is added to another mould made of steel, out of which they are taken polished and fit for use.

For the best sealing-wax, the best and most colourless shell-lac is used, the finest Venice turpentine, and the best cinnabar powder, or that of the natives of the Guiana. For the best black sealing-wax, the finest ivory-black is substituted for the cinnabar. For sealing-wax of inferior quality, not only the darker-coloured shell-lac is used, but other resins of less value, common common turpentine, and more, is added, as the deviations in these are now caused by such red lead alone, and lamp-black is used instead of ivory-black. Other colours are given to sealing-wax by mixing it with other substances, for the most part, different metallic oxides.

The sealing-wax, which is formerly in general use for sealing letters and legal documents, and which is still occasionally used for the latter purpose, consists of about four parts of bees-wax, one part of Venice turpentine, and as much cinnabar or other colouring material as is required to render it the tint which is desired.

Sealing-wax consisting of a red with a red colouring matter seems to have been first brought from the East Indies. The earliest seals of this material that have been found in Europe are of the date of about 1630. The composition of these was soon discovered by the Dutch, French, and Germans; and its superiority to bees-wax soon brought it into general use. The quantity of lac imported into this country, chiefly for making sealing-wax, is very great. (Lac.) The Dutch call it *zegel-lak*, and the Germans *ziegel-lack*; it is procured from the antlers or shell of animals; it is boiled in water, which, when cooled, is sufficient to melt the wax; it is then poured into a mould, which is at the top of a brazier, and cooled, and is finally polished. The French call it *cire-d-cacheter*; the softer material, which is really wax, they properly call *cire-d-sceller*. The name was probably given to sealing-wax by the French and English before its composition was known.

The Egyptians appear to have used for sealing a kind of earth, probably containing bitumen, which Hieredotus (ib. 38) calls sealing earth, *γαναυτικος*, on which an impression was made by a sealing-ring, *καυστριον*. A similar substance was used by the Romans (cretula); but the material commonly used by the antients, at least in later times, was wax.

(Beanbeck's History of Inventions, vol. 1; Dictionnaire Technique des Arts et Metiers; Handmaid to the Arts, vol. ii.)

**WAY.** Chimir (from the French Chemin), is a term used to denote either a right, in one person or more, of passing over the land of another, or the space over which a right in the former sense a way is an incorporeal right of the class called easements—the corporeal right, the ownership of the soil, and of all its products, superficial and mineral, remaining in the party in whom such ownership would have been, supposing no right of way to have existed, and it was also held as a personal right.

Five species of way are known to the law: 1, a footway, for persons passing on foot only; 2, a horse-way, for persons passing on horseback, but including a footway; 3, a drift-way, for driving cattle; 4, a carriage-way, for leading or driving carts and other carriages, always includi
A way of necessity is limited by the necessity out of which it has arisen. Thus, where the party to whom such a way is impliedly granted, or by whom it is impliedly recognized, becomes possessed of some other interest in the land, equally direct, the way of necessity is gone.

The particular rights of the grantee of a private way continue to exist notwithstanding the owner of the land may have dedicated to the public as a highway.

By the general enclosure act (41 Geo. III. c. 102) all roads, private as well as public, within the district, not set out by the commissioners, are declared to be extinguished.

The grantee cannot throw the burden of repairing the ways upon the grantor; and if the grantor is authorized to use the land, or has a right of way over it, the grantee is entitled to go upon the adjacent land, when the direct way is impassable. It is settled (Nott. & Selm., 367); whether he may so do where the state of non-repair is caused by the wrongful act of the occupier of the land, or where the liability to repair rests upon the latter, does not appear to have been decided.

If the occupant of the land on which a private way passes, or any other person, obstruct the way, the party entitled to the way may remove the obstruction, and he may also bring an action on the case, or, in some cases, an action of covenant against the obstructor. On the other hand, the grantor of the land must remove any right of way, by a grant of trespass against the person exercising the alleged right, the defendant may plead in justification a title founded upon prescription, grant, reservation, or statute.

II. Between public ways and public ways stand what may be called quasi-public ways, par-taking of the qualities of both, but differing, in some respects, from each. By some writers these are classed amongst private, by others, as public. They are more properly to constitute a distinct intermediate class. Sometimes the inhabitants of a town, &c. have immemorially used from their town, &c. to a church or market. A right of this description cannot, in modern times, be created. It must be hereditary, inter alia, as inhabitants, as such, are not at this day capable of taking any interest by grant; nor can it, like a public way, be created by dedication, as the dedication of a way can only be to the public at large. Such a right therefore can exist only by grant or prescription.

III. A highway is created where the owner of the soil has, by express words or by some act done or forborne, declared his intention that the public shall have the use of a way over such soil. The dedication of a way to the public is frequently created by statute, and also by the acts of the party, as the throwing down of fences, or from mere tacit acquiescence where the acquiring party is in possession of the land, and therefore has the means, if disposed so to do, of preventing the user of the way. The highway is usually created by statute, or the party dedicating should have a sufficient interest in the land to warrant such dedication. If he has a less estate than a fee-simple, his dedication will not bind the remissor. But it would also appear that the owner of such a limited estate could not even dedicate a highway to the public for the limited period of his interest in the soil, and that his attempted dedication, however distinctly and formally made, would amount to nothing more than a license revocable at the will of the owner.

Whenever there is no express dedication, the presumption of an intention to dedicate, arising out of the conduct of the party, may be rebutted; as by showing that when the public were first admitted a bar or a chain was occasionally thrown across the way, or the party forbade the use of the way. If the road be a continuation of a public road, the grantor must have the same extent of interest in the land and the way.

The party to whom a private road is allotted under the general enclosure act, has a statutory right of way. Where the party entitled to a way becomes the owner of an estate, the party passes across the estate, distinguished if the party has the same extent of interest in the land and the way. But if the one be held for an estate different in extent of duration from the other, the right is only suspended during the union of the two interests, and on the termination of the estate the right of way is extinguished by the unity of possession, it will, in some cases, revive upon a severance of that unity as by partition amongst parceners, &c.

A private right of way may also be extinguished by a deed of release executed by the party entitled to such a way, or by a declaration made by the party that he has no such right.
[Town] in which the way is situated. But particular persons may be liable to repair a highway. This special liability may exist by reason of enclosure (ratione coactionis), against parties who have enclosed the sides, or one side of the road, and have thereby lessened the facilities for breaking out into the adjoining lands where necessary; or by reason of the public lands (ratione tenentis territorii), which have by some means become chargeable with the burthen. In the case of a corporation aggregate, a liability to repair may also be established by prescription only, or antiquity, without enclosure or tenure.

An owner may sue another owner, whether a private or a quasi-public way, for the destruction of any part of a highway, and thereupon the court may grant an interlocutory or a final injunction, or it may direct the abatement of the obstruction, or award damages. If the perpetrator is a public officer, or a person acting under or by the authority of a public officer, the judgment is binding on the public officer, although not on the perpetrator. (§ 11.)

The regulation of the highway is a public and a general matter, and the liability to repair is a general liability. (§ 12.)

The regulation of the highway is a public and a general matter, and the liability to repair is a general liability. (§ 12.)

By the 23rd section of the act, no road or occupation way made at the expense of individuals or corporations, is to be deemed a highway which the parish is liable to repair, unless the road is made in a manner prescribed, and certain notices are given, and the road adopted by the parish. This provision does not, however, appear to shorten the right of the public to a highway dedicated to the public without the observance of the formalities here required for the purpose of throwing upon the parish a liability to repair.

The power of a way over water, either private, quasi-public, or public, if the course of the water alter by sudden or gradual change, the way is continued over the new course. Every navigable river, arm of the sea, or creek, is a highway for ships and boats.

WAY, LIVY. [Museum.] WAYS, ROMAN. Our old chronicle give this name to four principal ancient highways which they suppose to have been either originally formed by the Romans in Britain during their occupation of the country, or at least have been completed and perfected by that people upon lines of road for the greater part already traced and used by the former inhabitants. The names however by which the four highways are distinguished appear to be Saxo in form, although they may be Roman or British in etymology. One of them (the Ikenild) is supposed to have proceeded from Dover to Chester; or, according to another hypothesis, to Chester-le-Street, in Durham, passing through Canterbury, London, and Vernam, from which last-mentioned town it had also the name of Watling after the name of the Roman goddess of the same name. The second is called the Icknield-street or Icknield road, and is now called the Oxford Road at Tyburn, and proceeded to the west of Westminster, through Hyde Park and St. James's Park, to the Thames, which it crossed at Old Palace-yard. The common opinion however is, that it passed along the line of the road which is still called in London the Icknield-street or Icknield road. The third is called the Watling Street, and is supposed to have been the Romans's road from York to London, or its neighbourhood, is supposed to have been over Hampstead Heath, to Edgeware, and hence, through Verulam (or St. Alban's) and Dunstable in Bedfordshire, to Stoney Stratford in Northamptonshire, and to join the north-western road at Towcester, or at least, to be used by them. From this point its course is disputed, some making it proceed in a north-western direction to Chester, others carrying it due north to York and thence to Chester-le-Street; whence some imagine it to have been latterly extended to Lancaster and Fulkirk in Scotland, or even as far as to Caithness, at the extremity of the island. The Icknield or Lohenild Street is said to have been so called from its commencing on the eastern side of the island in the country of the Iceni, mentioned by Tacitus, and supposed to be the same with the Sinum of Ptolemy, who appear to have occupied Norfolk, Suffolk, and Cambridge. On the supposition however of London Stone having been the central milliarium where all the great roads of the country met, a branch of the Icknield-street is supposed to have passed through Aldgate, and to have been other wise known by the name of the Vicinal Way. The course of the Icknield to the westward is extremely obscure: nearly all that has been even conjectured on the subject is that it may have been continued in the same manner as the other roads of the same class, that it continued to be extended in the direction of Staffordshire to the western coast. It seems most probable that, while Watling Street ran directly north to Chester-le-Street, the Icknield Street, Thame, and Banbury, and the Bracelin or campaign road of the same name, would have passed through Aldgate, and to have been other wise known by the name of the Vicinal Way.

The course of the Icknield to the westward is extremely obscure: nearly all that has been even conjectured on the subject is that it may have been continued in the same manner as the other roads of the same class, that it continued to be extended in the direction of Staffordshire to the western coast. It seems most probable that, while Watling Street ran directly north to Chester-le-Street, the Icknield Street, Thame, and Banbury, and the Bracelin or campaign road of the same name, would have passed through Aldgate, and to have been other wise known by the name of the Vicinal Way.
which it may have entered that is now called Holborn.
Finally, the Fose is supposed (to have taken its name) from the beginning of the Totnes in Devonshire, and passing through Bristol, Gower (near which place it seems to have crossed Ermion Street, Chipping Norton, Coventry, Leicester, and Newark, to Lincoln. If it was carried from hence to London, probably by the Bishopsgate Street. Nothing however can be more obscure and uncertain than the whole subject of these supposed Roman highways. Camden treats it with a sort of contempt, declining to venture upon any pursuit after the course of the four parts of the road only, that the road; who will have only four ways of this sort, are in that, without any question, in an error.

The Itinerary of Antoninus makes fifteen itineraries or roads in Britain.

ATWODI, or WOYEVODA, is a Slavonian appellative from Vogno, 'war, and ovito, 'to lead'; and consequently it has the same etymology as the Latin Ducis, the Saxon Heretog, and the modern German Herczog.

This name was originally given to military commanders in different Slavonic nations; and, in Poland each palmate or province had its woyevode, whose duty was to command in time of war the pospolite, or ancient ban of his province. The woyevodes had in time of peace a certain administrative authority, and composed the first class of the military magnates of the time. The woyevodes were not in this respect superior in rank to the Comitum Palatii of the empire, they were translated in Latin by 'palatine.' [POLAND, Constitution q.f.]

In the earliest times of Russian history the appellation of woyevodes is given to high military commanders, and of which the Slavonic word woyevodes: the first were simply generals, and Peter the Great abolished this ancient Slavonian appellation and introduced that of general. The civil woyevodes were divided into provincial and town woyevodes, and they were governors of provinces and cities. This appellation was changed only under the reign of Catherine II. into that of governors, commandants, &c.

The appellation of woyevode was assumed for some time by the rulers of Moldau and Wallachia, who substituted for woyevodes the Greek title of despota, and finally its Slavonian translation, hospodar. The princes of Transylvania had also sometimes the title of waiwode, which was also given to some minor Turkish officers.

WEALDEN FORMATION, the uppermost series of the strata usually included by English geologists in the 'Oolite system.' [GEOLOGY.] This arrangement is justified by the plants, fishes, and reptiles which occur in its upper strata, for with the exception of a few species, more allied to oolite than to cretaceous types of structure. But as the Wealden deposits are of fluvial or origin principally, we do not find in them the usual shells or crinoids of the oolites, but a peculiar series, of which a few species are found in other deposits. The exact settlement in other countries which is contemporaneous with the fresh-water Wealden-beds, or whether any such equivalent is known, appears doubtful.

(Mantell, Geology of Sussex; Austin and Pitton, in Streets of Geol. Society, 1843.)

WEALTH is the means of obtaining the products of labour. An individual is rich or poor according to the quantity of the necessaries and luxuries of life which he can purchase; and the more or the less, the aggregate of his possessions, means of obtaining such advantages. Labour is the source of wealth, and every addition to its productivity tends to increase wealth, by lowering the cost of commodities, and rendering them more easy to be obtained. Political encouragements are the means of procuring the increase of national wealth, and of removing obstructions to its development; and it is the purpose of this article very briefly to enumerate and explain some of the chief principles of that science, which are directly connected with the production of wealth. The first object is to encourage industry. This is best done by leaving it free to obtain an adequate reward, by protecting all persons in the enjoyment of such reward, and in reducing the amount or value of it as little as possible. All attempts to secure or extend the enjoyment of wealth can only be effectually given in a free state, and under a civilized government, where property is secure, and labour free from restraint. Insecurity of person or property, arbitrary and oppressive taxes, monopolies, restrictions upon the free exercise of skill and enterprise, are all impediments to the increase of wealth: they discourage industry by diminishing the inducement to exert it, and they restrain its productive powers when exerted by thwarting the natural intelligence and activity of man in the pursuit of his own interest.

Whatever gives the best direction to industry, and facilitates its operations, is favourable to the increase of wealth. Thus the separation of men into different employments is highly recommended, as it develops industry in every branch, to the advantage of laborers in their respective arts, and causes a general economy of time. Still more useful is capital, without which division of labour cannot be extensively practised. It puts labour in motion; combines the work of many hands, and, by giving means to increased aid to human labour, and finally distributes its benefits, as it has assisted in producing facilities to the ready and effective application of capital obviously add to its utility; as credit, for example, which lends to one man the capital of another when he can employ it more profitably; and the various descriptions of money (the representatives of capital) which facilitate and cheapen the exchange of labour and its products between man and man. The higher the general rate of interest, the more capital is capital likely to be accumulated; because the majority of men are usually desirous of accumulating, and the means of doing so are evidently increased by high profits. If a profit of five per cent, upon a man's capital engaged in business of his own, by the time of his business without any diminution of his capital; a profit ten per cent, would enable him, at the same time, to add to it five per cent, annually, to be employed in further production and accumulation. It is clear that there will be no increase of capital, as long as in which the rate of profits does not leave a surplus beyond the necessary expenses of living. In such a case capital would be stationary, while the population to be supported by it would be on the increase, and the advantages of division of labour have already been noticed. The enriching properties of commerce are of a similar character. By distinct employments labour is made more productive; by commerce, the natural products and the peculiar arts of different countries are exchanged with mutual benefit and economy of labour to all. In France and Spain the grape, grown in the open air, provides delicious wine; in England, to make such wine (if it could be made at all), the grape must be grown in hot-houses. In England cotton goods are made by men of the world, in the country in the world. If France and Spain would buy them, they would save annually whatever excess of price they pay for similar goods made by themselves; while the capital and labour now applied to the Berlin cotton factories could be employed in the production of that article. To understand the effects of free commercial intercourse, it is only necessary to keep in view the analogy to the common dealings of life. No man thinks of making anything himself if he can buy it for less than he can make it. He continues working at his own employment, and buys the article he wants. If he did otherwise, he would lose his own profitable time and labour, and the article made by himself would take still more out of his pocket than if he had bought it; while its quality would probably be inferior, by reason of his own want of skill and practice in that particular work. The same principle applies to nations. Commerce extends to all countries the happy results of division of labour, instead of confining them to particular communities.

The last circumstance directly favourable to the increase of wealth, which need be noticed, is a cheap and expeditious communication, both in the interior of countries and with all parts of the world, for the carriage of merchandise. Every deduction from the cost of an article is an addition to the national wealth, and the expense of transit forms an essential part of the ultimate charges to the consumer. The extraordinary reduction of the cost of transport may be ascribed either to the exhaustible energies of a country. The extraordinary reduction of the cost of transport may be ascribed either to the exhaustible energies of a country. The extraordinary reduction of the cost of transport may be ascribed either to the exhaustible energies of a country. The extraordinary reduction of the cost of transport may be ascribed either to the exhaustible energies of a country.
aggregate time thus saved to the community at large would exceed 2000 years, or, in other words, the saving may be estimated as equal to the value of the labour of one man for 2000 years, or of 2000 men for one year. The importance of cheap and rapid modes of commercial intercourse, in other points of view, need not be pointed out.

Inasmuch as, then, the possession of a general knowledge and intelligence must be noticed as an agent in the production of wealth. It is the mind and the disciplined will of man which render all the circumstances of the world available for his benefit; and in view of education chiefly as a social blessing, we should never forget to urge its merits as a producer of wealth, upon those who would regard its other recommendations with less favour.

WEANING, the act of separating a child from the paternal breast and placing it in a bottle. Artificial feeding is recommended a few hours after the birth of a child, the breast of the mother secretes milk for its nourishment. The milk that is secreted at first differs in some of its properties from the milk subsequently secreted, and has been called colostrum. Healthy milk under the microscope is found to contain globules of various sizes, which are perfectly spherical in form, swarming in a fluid in which are suspended no other particles; whilst the globules of colostrum are irregular and disportioned, some of them being very large and others very small; they are freely colored in color of a yellowish, or a yellowish-green, colour, which are very minute, and which consist of fatty matter and a peculiar mucus. The milk retains these characters for several days, and it has been supposed at this period to possess a purgative property, which excites the bowels of the child. Milk which has been secreted at the fifth day is simply meconium. When the mother is healthy, the secretion of milk goes on abundantly till the ninth or tenth month, at which time the infant is generally able to take some other kind of food, and the process of weaning may commence at this period. It is generally deferred from ill health or other causes, that the mother is not able from the first to suckle her child. In this case the child must be either transferred to another nurse or fed artificially. There are two possibilities for the nurse to pursue. In the choice of a nurse care should be taken that the infant is transferred to one whose age, size, and temperament resemble its own mother. There should also be an absence of actual disease or a tendency to hereditary disease, and of all habits likely to interfere with a due secretion of healthy milk. Where children are artificially fed or reared from birth by the hand, the greatest care and attention are required. The first requisite is that the child should have a food as nearly resembling its natural food as possible. In all other respects the milk of the other animals has been employed. That of the cow, as being most easily obtained, is most frequently used; but it would appear that the milk of the ox has nearly resembles human milk, and on that account, where it can be obtained, is to be preferred. The milk of a horse is of a different nature, by Dr. Darwin, the milk of the ass, is as fair, of the milk of the cow, the ass, and the sea, and may serve as a guide in the preparation of the food of children:

The milk of the cow contains a much larger quantity of the casein, or nitrogenized principle, than that of woman or the ass, and requires dilution previous to its being administered to new-born children. At first two-thirds pure fresh water and one of cow's milk, with a small quantity of sugar may be employed. As the child grows older, the quantity of water should be gradually decreased till it takes milk alone. This food should be administered to the child at a temperature of about 88°, the heat at which the milk is produced by the mother. If the child is thus fed, a spoon should not be used, but some means should be had recourse to for administering the milk slowly, as the sucking-bottle, artificial nipple, &c. In feeding a child artificially, as in sucking, the first sign of insufficiency may be regarded as a sign that the child has had enough. On no account should children be fed again immediately after waking, a practice which is often extremely injurious.

If milk increases in size and strength, it requires in addition to milk, and at least ceases to require supplies from its mother. Although this is a perfectly natural process, it is often, from want of skill, or rather want of knowledge of natural laws, a source of painful disease to the mother, and sometimes even loss of life to the child. As a general rule, it may be stated that a child should never be suddenly weaned, and that the mother should allow the separation between milk and solid food of the better will be for both. The time for weaning must depend in some measure both on the development and health of the child and the state and health of the mother. With regard to the child, one of the first indications that weaning may be proceeded with is the appearance of milk teeth. This is indicative of preparation for other kind of food, and generally occurs in healthy children about the sixth or seventh month; and it is at this period that a gradual abstraction of the breast feeding will require sucking beyond the first year, although, where no ill consequences result to the mother, there is no objection to the child continuing at the breast till it is eighteen months or two years old. Where children are reared with some object in view, and present other signs of want of strength and delicacy of constitution, it is frequently advisable that they should remain a lengthened period at the breast. It is always necessary to take into consideration the health of the mother during the separation between milk and solid food, that an imperfectly secreted or diseased state of the milk which they would from immediate weaning, and under these circumstances of course the least evil is to be preferred.

In order that the weaning should be gradual, the child should be divided into two, or, if possible, three parts. On the first day, a little light food once or twice a day, and its supply from the breast should be proportionately diminished. If such a plan is pursued, the quantity of food administered by itself being increased whilst the supply from the nurse is diminished, it will not generally found the child will be experienced in entirely weaning the child at ten or twelve months old. After a child has been weaned its food ought principally to consist of liquid or semisolid substances. And for cow milk alone, or boiled with bread, thickened with ground almonds, or of a mixture given for the first few months. To these may be added, for the sake of variety, rice, tapioca, sago, and arrow-root, which may be made up with milk or water, or both; and water in the development of their teeth, and present other signs of want of strength and delicacy of constitution, it is frequently advisable that they should remain a lengthened period at the breast. It is always necessary to take into consideration the health of the mother during the separation between milk and solid food, that an imperfectly secreted or diseased state of the milk which they would from immediate weaning, and under these circumstances of course the least evil is to be preferred.

There is nothing better than bread and butter: but in all cases in the diet of children a due regard should be had to the time of life, and the constitution of the child. If the former are given in too great quantity, congestion and inflammation are frequently the result; whilst if the latter prevail in the diet, the child gets fat and loses strength, and becomes subject to diseases of debility. Neither the one nor the other kind of food can be administered by their judicious combination that the fatal effects of improper diet can be avoided.

(8) The genus Mustela of Linnæus, in the last edition of the _Systema Naturæ_, which underwent his revision, comprised the following species: _Mustela, Martes, Viverrina, Fitchius, Lutreola, Lutra, Lutreola, Bubo, Martes, Putorius, Furo, Zaluz, Erinnis, and Nivalis_. The genus thus established consisted of the Otters and Gluttons, as well as the true Weasels, and was placed between the Mustela and Ursus.

Cuvier divided the Martes (Mustela, Linn.) into the following subgenera:—

1. _Putorius, Cuv._

The animals of this subgenus are, he observes, the most mammalia of all and enough so that the canine has no internal tubercle; and their upper tuberculated tooth is longer than it is long; they have only two false molars above and three below. They may be recognized by the extremity of their muzzle, which is rather shorter and stouter than that

2. _Putorius, Cuv._
of the Martes; and they all diffuse a most disagreeable odour.

The species arranged under this subgenus are the common Polecat, Mustela sibirica, Linn.; the Polecat, Mustela euroripus, Linn.; the Polecat of Poland, Mustela sarmaatica, Pall.; the Siberian Polecat, Mustela sibirica, Pall.; the Wesel, Mustela vulgaris, Linn.; and the Boust or Ermine Wesel, Mustela erminea, Linn.

And approximated to these, he records the Mink, Norer, or Polecat of the Northern Rivers, Mustela tetracola, Pall., which frequents the banks of waters in the north and east of Europe from the icy to the Black Sea, feeds on frogs and crayfish, and has the feet a little palmated between the bases of the toes, but which its teeth and round tail approximates to the Polecat more than the Otter. It is reddish-brown, and has the circumference of the lips and under part of the jaw white. Its odour is only musky, and its fur very beautiful.

Some, Cuvier observes, think this the same as the Polecat of the North American rivers, Mustela vision, Gm., to which the name of Mink has been transferred, and which has also the feet semi-palmated; but this animal has generally while on the point of the chin only, and sometimes a narrow line under the throat, and is a different species.

Among the Polecats of warm climates, Cuvier notices the Javanese Polecat, Putorius mulepis, F. Cuv.; the African Polecat, Putorius africano, Desm.; the Striped Polecat of Madagascar, Putorius striata, Cuv.; and the Cape Polecat (the ZorilU of Buffon, Vivera zorilla, Gm.)

The Martes, or Martens, properly so called.
(Mustela, Cuv.)

These, according to Cuvier, differ from the Polecats in having an additional false molar above and below, and a small internal tubercle on their lower canine; two characters which a little diminish the cruelty of their nature.

Belonging to Europe, he notices, as very closely allied to each other, the Common Marten, Mustela martes, Linn., and Mustela foina.

As the production of Siberia, he calls attention to the Zibeline Marten, Mustela sibilina, so celebrated for its rich fur, which is brown, with some grey spots on the head, and is distinguished from the preceding by having hairs even under the toes, a provision adapted to its habitations in the most frozen mountains. The painful choice of this species is laboriously followed in the midst of winter among frightful snows, and to the pernicious with which it has been perservered in notwithstanding the meteoric terrors that surround the hunter, the discovery of the eastern countries of Siberia has been ascribed.

North America, observes Cuvier, produces many Martes, whose travellers and naturalists have indicated under the names of Pekan, Vison, Mink, &c. One of these, the White Vison of the furriers, Mustela luteocephala, Harl., has the feet as hairy and the hair nearly as soft as the Zibeline, but of a bright fulvous colour, and is almost white on the head. That, he remarks, which he shall call Pekan, Mustela canadensis, Gm., and which comes from Canada and the United States, has the head, the neck, the shoulders, and the upper part of the back minked with grey and brown; the nose, the rump, the tail, and the limbs are blackish.

The Mouffettes. (Mephitis, Cuv.)

These, like the Polecats, have two false molars above and three below; but their upper tuberculous tooth is large, and as long as it is wide, and their lower canine has two tubercles on its internal side, which approximate them to the Badgers, as the Polecats are approximated to the Grisons and the Gluttons. The Mouffettes have besides, like the Badgers, the anterior claws long, and adapted for digging, and they are even half-plantigrade; the resemblance is continued in the distribution of the colours. Cuvier truly remarks in conclusion, that in this family, remarkable for its felid odour, the Mouffettes are distinguished by a stench far exceeding that of the other species.

The Mouffettes, or Skunks, are generally striped with white upon a black ground, but the number of stripes varies in the same species. The most common is the North American species, Vivera putorius, Gm., which is black, with white stripes more or less wide and numerous, and the tip of the tail black. The odour of this suffocating animal has been compared to that of the Polecat, mingled with an overpowering stench of garlic; and nothing can be more intolerable. Cuvier also notices the Chineole

Teeth of Wesel, Zorilla, and Marten.

Upper set, a little more than twice the size of nature; lower set, nearly to the natural size.
(Pussera mephitis, Gm.), with the tail white; the stripes on the back sometimes occupy the whole of its width.

Mydas, F. Cuv.

Cuvier considers that this may be made a distinct subgenus. With the teeth, feet, and colours of the Skunks, it has a truncated muzzle in the form of a snout, and the tail is reduced to a small pencil of hair.

Only one species, Mydaus melinus, is known.

The Skunks. (Lutra, Storr.)

The Martes of Cuvier are placed between the Ratels and the Dogs.

The same position is assigned to this family by M. Lawson.

Mr. Swainson thus characterises the Mustelina, which he places between the Viverrina and the Ursina, in his family Mustelidae:—

Cutting-teeth 1-1 4-4 5-5

Canines, 2; Grinders, 5-5 or 6-6

one of which only is tubercular; head small, oval; ears short, round; body long, slender; feet short. The following are the genera which Mr. Swainson arranges under this subfamily—

Mephitis, Cuv.—Example, Pussera striata, Shaw.

Mydas, F. Cuv.—Example, Mydaus melinus.

Mydaus, F. Cuv.—Example, Lutra involuta, Storr.; L. latifrons, Cuv.; L. tridactyla, the common Otter. This genus comprises the subgenus Enhydra.—Example, Mustela latriss. The Sea Otter.

Gulo, Storr.—Example, Ursus gulo. Linn.

Eutamias, F. Cuv.—Example, Pussera mellitiera, Gm.—(Claviceps quadrupedula).—Mr. Bell, in his British Quadrupeds, makes the Mustelidae consist of the following genera:—

Lutra; Mustela; and Martes, Ray. Mr. Bell places the Mustelidae between the Ursidae and the Felidae in the same work.

Mr. J. E. Gray arranges his subfamily Mustelina, the fifth of his family Felidae, next to his subfamily Canina.

The Mustelina contain the following genera:—

Martes; Mustela; Putorius; Gymonops; Vison, Zoilla; Galera; Ratelus; Gulo; Helaeta; Mephitis; Chinchilla; Mydusus; Conusulus; Mydaus; Arctonyx; Meles; Taxidea; Lontra; Mustela; Aonyx; Piperomus; and Enhydra. (Symopsis: Brit. Mus.)

We shall confine ourselves to the Weasels properly so called, including the Martens, Skunks, and Mydas.

The dentition of the common Weasel, the Zoilla, and the Marten is very similar; and indeed M. F. Cuvier unites the three together for the sake of the slight variations that he observes, that the only difference that they present with reference to this part of their organization is that the Martens have in both jaws a rudimentary false molar more than the Weasel and the Zoilla, and that the Zoilla has the internal tubercle of the lower canine more developed than it is found in the analogous tooth of the Martens and Weasels or Polecats. In other respects their systems of dentition are quite identical.

EUROPEAN WEASELS.

(Mustela.)

Generic Character.—Body elongated, vermiciform; feet short; toes separate; claws sharp; molar teeth 5-5. Some error having obtained with regard to the species found in the British Islands, we shall select those species as examples:—

The Common Weasel, Mustela vulgaris. Specific Character.—Reddish brown above, white beneath; tail of the same colour as the body.

It has been considered as the common Weasel in the United States, is the ermine in its summer fur. Lawson notices it in his 'History of Carolina,' saying that it is the same as in England, but very scarce. Catesby also mentions it, writing 'Weasele;' and in the 'New Description of Virginia.' (1696), 'Weasels' are mentioned among their congeners, but with this saving clause, evidently written to fill a place, but these varmints driven out of my garden, or else eggs, at any time.' Dr. Richardson remarks that both the Weasel and the Ermine are indubitably inhabitants of the American continent, the Ermine extending to the most remote arctic districts, and the Weasel as far as the mouth of the Saskatchewan River. Captain Bayfield, he observes, presented the Zoological Society with specimens of the common Weasel, killed on the borders of Lake Superior, which agree in all respects with the European species; so Mr. Richardson concludes that the Stewardson, Carlton House. The last-named author adds that the Weasels of the fur countries become white in winter, like the Ermine, and are not distinguished from them by the traiders.

The Stout.'—Mr. Bell, who, in his interesting and carefully digested work on the British Quadrupeds, gives the above specific character of the common Weasel, well observes that the near approximation in figure and character, and the great general similarity in habits, which a comparison between the Stout and Wapiti presents, have occasioned considerable confusion in some of the accounts which have been given of their history, though the difference of size and colour would at once be sufficient to distinguish the species, there were no other points of disagreement between them.

'The Stott,' says Mr. Bell, 'is brown above, dirty white beneath; the tail always black at the tip, longer and more bushy than that of the Weasel, and the former animal is said to be more graceful as to its elegance and form. As against this, on the other hand, is red above, pure white beneath, the tail red and uniform. Their habits also, though generally similar, are, in many of their details, considerably distinct; and we are fully borne out at observation in saying that the account given against the Weasel of the mischief which is done to perpetrate in the farm-yard and the hen-coop, as well as amongst game of every description—on hares and rabbits, no less than on the feathered tribes—are principally due to the Stott. It is not meant to be asserted that the Stott will not, when occasion offers, attack the stock of the poultry-yard, or occasionally make free with a young rabbit or a sleeping partridge; but that its usual prey is of a much more ignoble character, is proved by daily observation.

Mice of every description, the field mouse, the water vole, rats, mice, ordinary food; and from the report of unprejudiced observers, it would appear that this pretty animal ought rather to be fostered as a destroyer of vermin, than exalted as a noxious depredator. Above all, it should not be overlooked that the Stott, ricks, opal, or farmer, is of great service in destroying the colonies of mice which infest them. These only who have witnessed the multitudinous numbers in which these little pests are found, in the various quarters of this kingdom, are specially, and better prepared, to acknowledge that the interior is sometimes drilled, as it were, in every direction by their runs, can at all appreciate the amount of their depredations; and surely the occasional abduction of a chicken or a ducking, supposing it to be even much more frequently chargeable against the Weasel than it really is, would be but a trifling set-off against the benefit, produced by the destruction of those swarms of little thieves.'

Mr. Bell adds, as ground for this defence of the Weasel, that a friend of his assured him that at least three buahes of various species of mice are destroyed daily by the clay-rick, a number that will not surprise those who have seen a good thoroughly-routing mouse-hunt in a grain rick-yard or granary where the mice have taken up their quarters in earnest. Great good the Weasel certainly does, and of a natural mode of attack. Dr. Richardson shows that small quadrupeds and birds form its staple. It inflicts a bite on the head, which pierces the brain, and seldom fails to lay the victor dead at its feet by a single blow. Not unfrequent can be seen a swarm of freshly-hatched gallinaceous and game-birds and young ducks, as well as the smaller feathered tribes; and that, although it does good service in keeping down the mice, it is a bad neighbour to the hare and rabbit-warren. Not that the Weasel will do one-third of the mischief that the Stott will, nor upon animals of such large growth, but it will do enough. It is a most active and persevering hunter; few trees will stop it when in search of birds' nests, which it robs not only by sucking the eggs, but by carrying...
off the young. It will hunt the Mole, the Field-Mouse, and other small quadrupeds in their usual haunts not only by the eye but also by the scent, like a Stoat; and amusing it is to see one of these flexible agile little creatures tracing up the scent when it is at fault. They will quarter the ground like a dog till they hit it off, and to no help from their eyes, will occasionally sit up, raising their heads, and examing their ears, and where at last will view around them. Their perseverance will tire down animals; larger and stronger than themselves; nor will water stop them when their game takes it for safety. In their plunge, and seldom quit their object till the fatal bite is inflicted. The brain of the victim is first eaten, and the body of the victim kept as a supply near the haunt of the little hunter; but it seems very questionable whether they are addicted to those blood-sucking propensities which the vulgar attribute to them; and our own experience confirms the extreme length of the head and body, and most habit to be much exaggerated, and whose own observation, as far as it had gone, tended to confirm the opinion of those who deny the existence of such a propensity altogether.

The last-named acute zoologist also throws well-grounded doubt on the assertion that the Weasel will attack and destroy snakes; and indeed he believes such a notion to be entirely erroneous. He placed a weasel and a common snake together in a large cage, in which the former had killed and eaten one of them, in the winter, with which it slept. Mutual fear was manifest, and the animals kept a distance; the snake however showing as much disposition to be the assailant as the weasel, which at first generally kept close to the ground. The sight of the weasel in the day, without however materially injuring the reptile, and evidently without any instinctive desire to feed upon it. After they had remained two or three hours together, the animals appeared almost indifferent to the presence of each other. The snake was then removed.

"How different was this Weasel's conduct," says Mr. Bell, after relating the experiment above stated, "when a mouse was introduced into the cage: it instantly issued from its little box, and in a moment single bite on the head pierced the mouse dead without a struggle or a cry. I have observed that when a Wessel seizes a small animal, at the instant that the fatal bite is inflicted, it throws its long little body over its prey, so as to secure it should the first bite fail; an accident however which I have never observed to occur when a mouse has been the victim. The power which the Weasel has of bending the head at right angles with the long and flexible, though powerful neck, gives it great advantage in this mode of seizing and killing its smaller prey.

The weasel's habit is to seize a victim and destroy it. We have all heard the story of the eagle and cat, and how the maddened quarry brought the mighty bird that had snatched it down again to the earth in the agonies of death. In the 'Magazine of Natural History,' a similar anecdote is given of a weasel and an eagle, with any strong voucher. But Mr. Bell, on the authority of Mr. Pindar, residing, when the event occurred, at Bloxworth, in Dorsetshire, relates the following passage in the life of a weasel; and as there is no ground whatever for doubt, it affords a striking instance of the murderous instinct of this little quadruped.

Mr. Pindar, while riding over his grounds, saw at a short distance from him a kite pounce on some object on the ground and immediately take it up. He then observed that the kite began to show signs of great uneasiness, rising rapidly in the air, or as quickly falling, and wheeling irregularly round, whilst it was evidently endeavouring to force some obnoxious thing from it with its feet. After a sharp bite, it made off, as if to fly from a foe. But the kite was farther from where Mr. Pindar was instantly watching the manœuvre. He instantly rode up to the spot, when a weasel ran away from the kite, apparently unhurt, leaving the bird dead, with a hole eaten through the skin under the wing, and the large blood-vessels of the part torn through.

With similar courage the Weasel will attack dogs, and even men, when its nest is invaded. This is framed of dry leaves and herbage, and is generally lodged in some snug hollow, such as the hole of a tree, a bank, or a dry ditch, which keeps it warm and comfortable. Here four or five young are brought up from each birth, and the number of these litters is two, or even three, in the year.

The female weasel is smaller than the male, and Mr. Bell well observes that it is probably the 'little reddish beast,' called by the country-people a Gane, mentioned in White's 'Selborne,' and described as not much bigger than a Field-Mouse, but much longer. Mr. Blyth informed me that the animal was known in Surrey by the name of Kine.

This species sometimes, but rarely, turns white in the winter, and in this state it is the Mustela nivalis of LINNAEUS. Mr. Bell received one from Scotland with two white spots on each side of the nose, which it retained throughout the summer.

Pennant gives the following national names for this species:—Browne of the British; La Bellette of the French; Donnola, Balistola, and Benula of the Italians; Comadreta of the Spanish; Domina of the Portuguese; Weasel of the Germans; Weezel of the Dutch; Vesel of the Swedes; and Vessel of the Danes.

The Anglo-Saxon name is Wesle.

Mr. Bell has, very properly, in his opinion, chosen to retain the generic term Mustela for the present form, in preference to Putorius, Cuvier's subgeneric name, because he considers it as the type of the family. The general form and aspect of the Weasel, he observes, show it to be typical in the group of vermine carnivora. The body is extremely slender and arched, the head small and flattened, the eyes black, and remarkably quick and lively; the ears short and rounded, the neck very long, but little shorter than the trunk, and very flexible; the tail short, not one-third the length of the head and body; smaller than that of the rest of the genus, and without the terminal tuft of long hair which exists in the Stoat; legs short and furry to the end of the toes; fur short and close. Length of head and body of male 8 inches 3 lines; of tail, 2 inches 4 lines. Head and body of female, 7 inches; tail, 2 inches.
colour in the existing fur; and he cites, in proof of this view of the subject, the case of the Hudson's Bay Lemming, which, in Captain Sir John Ross's first Polar expedition, was exposed in its summer coat on the deck to a temperature 30° below zero, and the next morning the fur on the cheeks and tip of the tail was as white as the snow. But the change was completely lost in the next winter; the animal was not seen in summer dress in the next year. Another instance of this is the Stoat, so all white. Next day the shoulders had considerably extended, and the posterior part of the body and flanks had turned to a dirty white. At the end of a week the winter change was complete, with the exception of a dark line along the shoulders, which in the spring became perfectly white. Next day the shoulders had considerably extended, and the posterior part of the body and flanks had turned to a dirty white.

Mr. Blyth, however, informed Mr. Bell that he had come to a different conclusion, and was of opinion that authors who have observed the marks on each shoulder for had been in a manner changed in autumn; for in a specimen which Mr. Blyth had lately examined, and which had been killed during the autumnal change, it was clearly perceivable that the white hairs were all new, and not the brown changed in colour. Mr. MacGillivray, too, a close observer, says that the change is not effected by an alternation in the colour of the same hairs, but by the gradual subdivision of brown for white hairs.

He states that a male killed on the 30th March had on the breasts and sides a broad band of brown and white; and the tail, a broad band of brown, interspersed with white hairs; and the brown hairs were all much shorter than the white. A female killed on the same day in company with the male had the upper parts all brownish-red, but paler than those of the male; and the white hairs, interspersed; but its fur was not shorter than that of an individual killed in December. In the former case, Mr. MacGillivray observes, the summer change had commenced, and the winter coat not yet adopted; in the latter case, the winter coat had not assumed a white colour, and still remained. He states that a female shot at Loanhead, near Edinburgh, in the end of February, 1832, was brown above, with a few white hairs, especially at the ends of the tails. The body was covered with mild winter, and the animal had not assumed its white winter fur, for the red hairs did not seem to be new. 'On the whole,' says Mr. MacGillivray in continuation, 'it appears to me that in spring and the beginning of summer, when the sun is at its highest, the white hairs are produced, and that all the red hairs that appear are new. Towards December, earlier if the weather be very cold, later if less so, the hairs of the upper parts become white. In an individual obtained in December, 1834, the colour was a mixture of white and brownish-red. The hairs of the latter colour were not in the lowest degree faded, and those of the former were much shorter, and evidently just shooting; so that the change from brown to white would seem to take place by the growth of new hairs, and not by the shortening of those of the summer dress. But in mild winters the hairs retain their red colour; and if new hairs come in, they are also red: if the weather become colder, the new hairs that appear are white, although the old hairs do not vary; and if there are alternations of severe cold and temperate weather, the animal becomes mottled. It is certain that the change of season is not regularly attended with a change of colour; that great cold at any period of winter, if protracted, is accompanied with a change of white, but there is no evidence that a return of heat produces a return of the red colour in white hairs. The hairs continue to elongate from the end of spring to the beginning of winter, and the fur is certainly not longer in winter than in spring. Perhaps the same may be said of the autumn; but the animals grow in mild weather are brown, while those that shoot out in cold weather are red, cold having the effect of changing the structure of growing hairs, or of acting on their bulbs so as to prevent the application of colouring matter.

We have given this detailed account in Mr. MacGillivray's own words, and of the accuracy of it there can be no doubt. Still the experiment made on the Hudson's Bay Lemming change was only empirical, and it was impossible to prevent the possibility of attributing it to anything but a change of the hair actually in existence, seems conclusive in favour of Mr. Bell's opinion, in some cases at least. Indeed Mr. MacGillivray himself admits, in the same account of the same part of the country, that something new on the brown hairs themselves, on the application of intense cold, become whitened; and he states that he has seen individuals of a brown colour patched with white, in which the white hairs were of the same length as the brown; but he adds that he had never met with any of which the hairs were partially coloured, or appeared to be changing from brown to white, still less from white to brown; and he concludes 'that the change from this animal sheds the fur gradually, and in small parcels or patches, all the year round, in the same manner as partridges shed their feathers, and that so long as the weather is mild, the growing hairs are brown, on the one hand, but while with it is very cold. That in March, 1834, I was presented by Mr. Ferguson, of Raith, with a most beautiful specimen, on which there was not a single red hair. As to the change effected in coloured hair by intense cold, a separate experiment we are to believe concerning it, and as yet ermines have not been subjected to this kind of observation.'

That change of temperature, and not merely change of season, is necessary to affect the alteration of colour, is evident from Mr. Hogg's observations, which will be found partly in the 5th vol. of Loudon's 'Magazine of Nat. Hist.' and partly in the work above quoted of Mr. Bell, who received a letter from Mr. Hogg on the subject after the publication of the 'History of the British Quadrupeds.'

Mr. Hogg, whose remarks appear to have been made in the county of Durham, states that within the last nine years from the date of his communication he had met with two Ermines alive, and in the most different winters that have occurred, in a gross of Ermines which he kept in the extremely severe winter (January to March) of 1823: the other in the extremely mild January of 1832.

In consequence of the months of December, 1831, and January, 1832, and 1833, were so nearly, and so long, that the nearly equally, there was no snow; and he says Mr. Hogg, 'greatly surprised to find this stoat clothed in his winter fur; and the more so, because I had seen, about three weeks or a month before, a stoat in its summer cost or brown fur. I was therefore naturally led to consider whether the reappearance of the winter coat, and the brown and white stoats seen by me this warm winter inhabited, could alone account for the difference of the colour of their fur, in any clear and satisfactory manner. The situation then where the stoat was seen, is in lat. 54° 29' N. nearly, and long. 1° 33' W. It is an island at a very considerable elevation, and in the immediate neighbourhood of the loamy moorlands called the Hambledon Hills. These constitute the south-western range of the Pennines, and are situated about 1200 feet above the sea. At the time, the Ermine was making his way towards the hills, where, no doubt, he lived, or frequently haunted; and consequently the great coldness of the atmosphere, even in so mild a winter, upon so elevated and bleak a spot as that moorland, would satisfactorily account for the appearance of the animal in its white fur; although the place is, in a direct line, more than twenty-three miles distant to the south of the fields near the Tees, inhabited by the Brown Stoat.' The Ermine inhabits the treetops of the head and body is nine inches ten lines, the tail being four inches eight lines, is the Carunc of the antient British; Stoat, Stoat, and Greater Weasel of the modern British; L'Hermine of Le Rouge de l'Armorial. In the Spanish: Amino and Armelina of the Spanish; Hermelin of the Germans; Hermelin and Lokati of the Swedes; Hermindly of the Dutch; Hernalin and Lokat of the Danes; Heremone and Shacoahew of the Cree Indians; and Terreya of the Esmaraux.

Geographical Distribution.—Temperate Europe generally, but common only in the north. The finest, that is, those with the longest and thickest fur, and of the purest and brightest colour, are imported from the high latitudes. Russia, Norway, Siberia, Lapland, and various other parts of northern Europe. From the Canada imports in the year of 1833, 506,348. In America it is found from the most northern limits to the middle districts of the United States. Ermine-skins are also found in various parts of Europe, but not so common as in Canada; and there is a voice; but they have so sunk in value, that they are said not to repay the Hudson's Bay Company the expense of
collecting them, and very few are brought to this country from that quarter.

*Hodie,* &c.—It appears that in England generally, says Mr. Macgillivray, *the Ermine is less common than the Wessel; but in Scotland, even to the south of the Frith of Forth, it is certainly of more frequent occurrence than that species; and for one Wessel I have seen at least five or six Ermines. It frequents stony places and thickets, among which it finds a secure retreat, as its agility enables it to outstrip even a dog in a short race, and the slimmess of its body allows it to enter a very small crevice. Patches of hare, in particular, afford it perfect security, and it sometimes takes possession of a rabbit's burrow. It preys on game and other birds, from the grouse and ptarmigan downwards, sometimes attacks poultry or seeks its eggs, and is a determined enemy to mice. Young rabbits and hares frequently become victims to its rapidity, and even full-grown individuals are sometimes destroyed by it. Although in general it does not appear to hunt by scent, yet it has been seen to trace its prey like a dog, following its track with certainty. Its motions are elegant, and its appearance extremely animated. It moves by leaping or bounding, and is capable of running with great speed, although it seldom trusts itself beyond the immediate vicinity of cover. Under the excitement of pursuit however its courage is exerted to the greatest advantage by the thought of death beguiled to a grouse, hare, or other animal strong enough to carry it off, and it does not hesitate on occasion to betake itself to the water. Sometimes when met with in a thicket or stoney place, it will stand and gaze upon the intruder, as if conscious of its own superiority, and although its boldness or exaggerated in the popular stories which have made their way into books of natural history, it cannot be denied that, in proportion to its size, it is at least as courageous as the tiger or the lion. 

Mr. Bell was informed by the Rev. F. W. Hope that the latter, while shooting in Shropshire, was attracted by the loud shrill scream of a hare which he thought had been just caught in a poacher's snare. He ran towards the spot, and there saw a hare limping off, apparently in great distress, with something attached to the throat of a stoat. This proved to be a stoat, and the stamch hare made its way into the brushwood with its enemy still holding on. In England it takes advantage of the galleries of the mole for its winter retreat, as well as the rabbit-burrow.

Captain Lyon, R.N., saw the Ermine hunting the footsteps of mice in the north as a hooded hunt a fox, and observed their burrows in the snow, which were placed up in as large a circle as those of the common polecat in Britain. These passages ran in a serpentine direction, and near the hole or dwelling-place the circles were multiplied as if to render the approach more intricate.

The same graphic voyager gives a lively description of an Ermine in the open field. As a stoat, the moment he obtained daylight in his new dwelling, he flew at the bars, and shook them with the greatest fury, uttering a very shrill passionate cry, and emitting the strong musky smell which I formerly noticed. No threats or terrors could induce him to retire to the sleeping-place, and whenever he did so of his own accord, the slightest rubbing on the bars was sufficient to bring him out to the attack of his tormentors. He soon took food from the hand, but not until he had first used every effort to make the food conveyed to him. This boldness gave me great hopes of being able to keep my little captive alive through the winter, but he was killed by an accident.

Dr. Richardson states that the Ermine is a bold animal, and even domesticates itself in the habitations of the fur traders, where it may be heard the live-long night pursing the white-footed mouse (*Mus leucopus*). He remarks that, according to Indian report, this species brings forth ten or twelve young at a time. In this country it produces about five in April or May.

*Chuze.*—In Siberia Ermines are taken in traps baited with flesh; and in Norway they are either shot with blunt arrows, or taken in traps made of two flat stones, one being propped up with a stick, to which is fastened a length of string. This the animal nibbles when the stone falls and crushes it. Two logs of wood are used for the same purpose and in the same manner in Lapland.

P. C. No. 1700.

---

*Ermine in summer dress.*

*The Polecat, or Petchet Wessel, Mustela putorius.*

Description.—Slutter in proportion than either the common Wessel or the Ermine, and the head broader. Nose rather pointed, ears round and not conspicuous. Neck comparatively short. Tail inclining to bushy, rather more than a third of the length of the body and head.

There are two kinds of fur in this species; the short is fulvous and woolly, the long is black, brownish black, and shining. A brown colour mingled with yellow, varying according to the proportions of these two sorts of fur in the individual, is the result. There are some white marks about the mouth and ears, and the parts which are darkest in colour are the head, tail, and feet. Length of the head and body 1 foot, 5 inches, 6 inches; of the tail, 5 inches 5 lines. Such is Mr. Bell's measurement. Mr. Macgillivray makes the total length to the end of the tail 17 inches, and observes that the anal sac is usually represented as single; but he found that beneath the extremity of the rectum externally two sacs containing a yellowish fetid substance of the consistence of thick cream were present.

This is the *Ejefjeldi* of the ancient Britsh; *Falumar,* *Fomart* (as well as the terms given at the head of the description) of the modern British. *Polecot* has been supposed to have been a corruption of Polish Cat; but this seems to be not much better than a guess; *Pomarti* and *Falimar* have with better reason been considered to be contractions of *Poult Martin,* in contradistinction to the *Street Martin.* It is the *Putois* of the French, *Forta* and *Puzolo* of the Italians, *Putoro* of the Spanish; *Ilte, uh,* and *Dunning* of the Germans; *Houling* of the Dutch; *Ille* of the Swedes, and *Ilder* of the Danes.

Geographical Distribution.—Europe generally. Pen- nant says that it is common in the temperate parts of Russia, but grows scarcer in Siberia, except in the desert of Baraba and beyond the lake Balakat.

*Habits, &c.*—The Polecat is most destructive to the poultry-yard and the preserve; its appetite for slaughter, which seems never to be satisfied as long as any living thing remains within its reach, rendering it a most ruinous neighbour to those who rear fowls or keep up a head of game. Not only the young birds fall victims to it, but the parents also; nor are even geese or turkeys safe. We remember an instance of a hen and a whole brood of

*Vot. XXVII.*—V
chickens being killed by one of these destroyers in a single night; and upon another occasion, seven or eight nearly full-grown turkeys. The brain and the blood seem to be the choicest portions. The bodies of the dead are carried off to its haunts, which are generally in some cope or wooded part a snug or in the heart of a preserve, whence it issues on its deadly errand in the evening, generally soon after sunset, or when it grows dusk. It is bold and daring withal. Mr. Nevill Wood, ofoston Hall, in Derbyshire, informed Mr. Bell that some years ago he had ten fine young ducks, which were shot up every night in a small outhouse, destroyed in one night by a polecat. On entering the place in the morning, Mr. Wood found every duck lying dead, each with a hole in the neck; and in a few moments the perpetrator of the bloody deed marched towards him, licking its jaws without exhibiting the slightest alarm.

No 'vermin' is placed with more satisfaction upon 'The Keeper's Tree,' for none commits more havoc, if so much, among the game. Beginning with the egg, it persecutes all the game-birds through every period of life, and is a far more determined enemy than the Stoat itself to the hare and rabbit-warren. The fox, as is well known, will do much to keep down the phasians, and especially the rabbits and hares; but even this wily and powerful invader is not so mischievous as the species of which we are treating. Where a fox will kill one, a polecat will immolate ten, to say nothing of egges; no vertebrated animal seems to come amiss to its murderous nature. Bewick relates that in the spring its nest was found in the snow from the side of a rivulet to its hole at some distance from it. As it was observed to have made frequent trips, and as other marks were to be seen in the snow which could not easily be accounted for, it was thought a matter worthy of great attention. It after the accounts examined, and five fine eels were discovered to be the fruit of its nocturnal excursions. The marks in the snow were made by the motion of the eels in the quadraped's mouth. In Loudon's 'Magazine' (vol. vi.) is an account of a female polecat that was hunted to her nest, which held five young ones in a comfortable bed of withered grass. From a side hole the narrator picked out forty large frogs and two toads alive, but capable of sprawling only, for the old polecat had stricken them all with palsy by a bite through the brain of each.

The nest of this species is generally made in some rabbit-burrow, in the crevice of a rock, or where the tangle hedgerow and brushwood overgrow loose heaps of stones, and there the female drops from four to six young in May or early in June. The courage of the Polecat is great, and none of the tribe denominated by gamekeepers 'vermin' so severely tries the 'pluck' of a terrier; for its flexibility, unless seized in the right place and shaken to death at once, enables it to turn and fasting upon the nose of the dog, so as to make the latter not unfrequently desist from the attack.

The Polecat.

Pennant remarks that warrens assert that the Fitchet or Polecat will breed with the Ferret, and that they are sometimes obliged to procure an intercourse between these animals to improve the breed of the latter, which by long confinement will abate its savage nature, and become less eagar after rabbits, and consequently less useful. "Mr. de Buffon," says Pennant, in continuation, "denies that it will admit the Fitchet, yet gives the figure of a variety under the name of the Polecat (La Preure Polecat), which has much the appearance of being a spurious offspring. To put the matter out of dispute, the following fact need only be related. The Rev. Mr. Lewis, vicar of Llan-owel, in Caermarthenshire, had a tame female Ferret, which was permitted to go about the house; at length it absented itself for several days, and on its return proved with young; it produced nine of a deep brown colour, more resembling the Fitchet than the Ferret. What makes the matter more certain is, that Lewis had no males of this species for it to couple with, neither wild nor domestic, 

inferior to the fur of the Sable or Marten, that of the Polecat is nevertheless esteemed, and a considerable import of it is made to this country from the north of Europe, under the name of Fitchet.

Genus Martes (Ray).

Generic Character.—Grinding teeth 5-5; 6-6.

Some indeed read 'mele' for 'marte,' and so make a badge of the capture. The amatorius in the Delphin (vol. i.) has been added as much to his illustration of that reading, for he writes, 'Legit allia capita mele, Gallicum alaibere, chat savauge, fouine.'—badger, wild cat, marten, for which last 'fouine' is the French term.

George Bauer, who wrote under the name of Agriculturist in his book De Animalibus Subterraneis, notices the three kinds of marten first above alluded to. After writing a clear account of the Polecat, he says: 'A third kind of sylvan species lives in the caverns of rocks and caverns, which is called Martes by Martin and Martes der Germans.' He then gives Martin's line above quoted, and proceeds to describe the animal and its habits with much accuracy. This is the Common or Stone Marten. He then describes the Polecats (the Polecat and Fitchet) as being the fifth, 'called by the Germans Zobel,' the Sable. The skins of the last are, he remarks, more precious than cloth of gold, and he adds that forty of the best, the usual number in one bundle, have been sold for more than a thousand pounds of the (Folio, 1743).

Geneser, Aldrovandus, and Joneston did little more than copy Agriculturist. 'They seem however,' says Mr. Bennett, who has well traced up the opinions of authors upon this subject, 'to have abandoned Agriculturist's subdivision of the second species and to have described the Polecat under the name of Marten, as it was emphatically denominated by the Germans, as the Beech Marten, imprinting to it a more familiar and sociable disposition, and a fondness for the neighbourhood of inhabited places. The same distinctions are adopted by Ray in his Synopsis Generum 1683; but to his description of the Sable he adds that Dr. Tanner Robinson had seen the animal itself in the possession of Dr. Charlton. Its size was that of a cat of Cyprus. Its colour darkly tawny; the fore part of its head and its ears of a whitish ash-colour; and the tufts on its eyebrows, nose, and face very long.'

Mr. Bennett remarks in continuation that so lightly did Linnaeus estimate the value of the distinctions indicated between the Pine and Beech Martens, he has uniformly treated them as one and the same animal in all his subsequent writings, from the first edition of his Systema Naturae to the twelfth of his Species Naturae. It is only, he observes, in the last, that Linnaeus for the first time intimates the existence of any difference between them. There he
speaks of two varieties as known to the rustics—the Beech Marten with a white throat, and the Pine Marten with a yellow throat. The Linnaean character of the Sable is principally, Mr. Bennett adds, founded on that of Ray, and is accompanied by the sign used by Linnaeus to denote that he had not seen the animal to which it is appended.

Klein (1751) keeps the old descriptions of the three species. Brisson (1760) distinguishes the Beech and Pine Martens, and expresses himself about the colour of their throats; but he describes the Sable, which he had not seen, from Ray and the more antient writers.

Daubenton evidently doubted whether to consider the Beech and Pine Martens as distinct species or varieties only, observing that the one resembles the other so closely, that the colours of the fur form the sole distinction. He describes the Pine Marten as having the throat yellow, and the Beech Marten as being white in that part. The difference of the species, he says, "is the same as that which Bennett had observed the same fact. And lastly, even the comparative length of the tail, on which the greatest stress is laid, affords no absolute criterion; for Pallas himself, Mr. Bennett remarks, states that this organ is a little longer in the males, at least when young, than in the females; must however," says Mr. Bennett, in concluding this part of his careful treatise, "be allowed to outweigh all such considerations; and to indicate the existence of a true sable, as a distinct species from the martens, although unknown to later zoologists.

The name of Pallas undoubtedly carries great weight with it, and justly, but still cases of this description ought not to be argued too much on authority.

But to return to the opinions of authors: M. Lesson encompasses all the martens under the epithet of the *Marte commune*, *Mustela marces*, *Linn.*; *La Marte, Buff.* 2. *Marte Fontine, Mustela fonta*, *Linn.* (Gmel.?), *La Fontine, Buff.* 3. *Marte zibeline, Mustela zibellina*, *Linn.*, the *Sobol of the Poles and Russians*; the *Sable of the Swedes*. The latter three species have been almost universally enumerated by authors, each copying his predecessors with more or less correctness. Desmarest, he remarks, has omitted the most important characters given by Pallas for the Sable, and has, on his own authority, furnished it with a tail of two-thirds the length of its body, while that of the Pine and Beech Marten is stated to measure but little more than the half; and he says that he knows of but one instance, since Linnaeus, in which the fore-legs and the tail may have been perfectly conjoin'd. This occurs in Dr. Walker's "Essay on the Scottish Mammalia." Dr. Walker indeed, Mr. Bennett observes, does not mention the former, and possibly may not have regarded it as a native of Scotland: he characterizes the fore-legs and the tail in the same manner, and observes that as the animal advances in age the throat becomes yellower.

Mr. Bennett, in the Gardens and Menagerie of the Zoological Society, where the above inquiry is carried out, found the Sables, *Pine Marten, Mustela marces*, under the Appendix, *Mustela fonta*, under the name of *Mustela*, and the *Marte zibeline*, *Mustela zibellina*, *Linn.*, two individuals which were sent from Russia to the late Marchioness of Londonderry, as specimens of the true sable, from which, as described by Pallas, they were at once distinguished by a well-defined yellow patch, spreading from their chest and throat, and by the length of their tail, which considerably exceeded that of their hinder legs. "Their colour," says Mr. Bennett, "during the winter was, with the exception of the throat and the margins of the ears (which were likewise yellow), of the colour of the winter sable, with their hair extremely long and fine. The fore-legs of one of them were crossed in front towards the upper part by a yellowish stripe. In the summer they assumed a much lighter tinge, and their hair became so much shorter as to make the existence of being scarcely more than half their former bulk. The extremities of their toes, which had been well protected by lengthened wool throughout the cold weather, were also stripped of their covering, and their skin generally. In manner they were lively, active, and good-humoured; they slept much during the day, but frequently indulged in whirling themselves, half climbing and half leaping, round the inside of their cage, with such rapidity as almost to elude the eye." Mr. Bennett goes on to state that the museum in Bruton Street contained five more specimens of the group.

Y 2
besides those which obviously belonged to species distinct from the animals under consideration. Two of these might, in his opinion, be fairly referred to the Beech Marten in its winter and summer dress; but both were approach to the Pine Marten even in this supposed distinguishing character, which is far from offering any help towards a satisfactory solution of the difficulty.

Mr. Macgillivray notices these observations of Mr. Bell in the Zoologist's Library (British Quadrupeds); and then states that the examination of individuals in different stages, and obtained in various parts of Scotland, had disclosed to him a gradation of colouring combined with a sameness of form that had satisfied him as to the individuality of the species. In fact, says Mr. Macgillivray, the “beech marten” and the “pine marten” differ less from each other as to size than individuals of the polecat, ermine, or weasel, and the differences of colour observed are not greater than in the common fox. The former, var. with the white throat, Linn.; Mustela foina, Gmel.; Martes furorum, Ray.; Martes saxonum, Klein. Mr. Bell describes the head of this marten as somewhat triangular; the muzzle pointed; the nose extending a little beyond the lips; the ears large and tending to be lower in the males than in the females; the tail large, open, and rounded; the body much elongated and very flexible; the tail long, thick, and somewhat bushy; the feet rather short; the toes generally naked, but at times, probably in the winter, covered beneath with a thin soft hair. The fur, he observes, is of two sorts: the inner extremely soft, short, copious, and of a light yellowish grey colour; the outer very long, shining ash-coloured at the roots, brown at the extremity, but of a yellow tinge at the lower part of the body; the middle of the back, the tail, the outer parts of the legs and the feet being darker than the other parts; the belly lighter and more grey; the throat white, but Mr. Bell states that in one instance he had seen it of a dull yellow tinge. Inset: A specimen of the pine marten with a length of head and body 1 foot 6 inches; of the tail 9 inches 6 lines.

This is the Bela grays of the ancient British, and Stone Marten of the moderns. It is La Fouine of the French; Poma and Puma of the Maltese; Martes and Golfinis of the Spanish; Hausser Marder and Stein Marder of the Germans; Marter of the Dutch; Mard of the Swedes; and Maas of the Danes.

Geographical Distribution.—Northern and Temperate Europe. Western Asia.
woods, though it is often met with in them, and more frequently in mountainous and stony places, and nearer the habitations of man, than the Pine Marten. It prefers the vicinity of farm-yards and homesteads, and is a ruinous visitor to them and the game-preserve. It is an expert climber, and Daniel, in his Rural Sports, has figured it on a tree about to attack a hen pleasantly at perch. A very generous rod has been added to this was the Pine Marten in a state of domestication. It is lively, active, and graceful in its movements. The nest of the female is constructed of herbage, straw, or grass, sometimes in the hollow of a tree, sometimes in the crevices of rocks, not unfrequently in a ruin, and occasionally in granaries or barns.

The fur of the Beech Marten is considered very far inferior to that of the Pine Marten, and is known in the trade as the skin of the Stone Marten. Many are imported from the north of Europe, and do not represent Sable. The comparatively poor quality of the fur however is immediately perceptible to the experienced eye, although, as is the case with most of the animals which are used for their fur, the northern skins are fuller, richer in colour, and more lustrous than those from more temperate climates.

The Pine Marten.—Martes obesus, Ray; Mustela martens, Linn. Brown; throat yellow; toes naked beneath; legs longer and limb smaller than in the Beech Marten.

Habits, &c.—The Pine Marten in its habits resembles the Beech Marten, but it shuns the neighbourhood of man—living in Europe in deep forests, and preying on birds and the smaller animals. The female deposits two or three young ones in a nest of moss and leaves formed in some hollow tree, when she does not take possession of that of the squirrel or the woodpecker.

Dr. Richardson states that the Pine Marten inhabits the woody districts in the northern parts of America, from the Atlantic to the Pacific, in great numbers, and that it has been observed hunting both in the depth of winter and when the trees have been killed by fire, but are still standing. ‘It is very rare,’ continues Dr. Richardson, ‘as Hearne has remarked, in the district lying north of Churchill River, and east of Great Slave Lake, known by the name of Chippewa or Barrier Lands. A similar district, on the Asiatic side of Behring’s Straits, twenty-five degrees of latitude in breadth, and inhabited by the Tchntski, is described by Pennant as equally unfrquented by the Marten, and for the same reason, the want of its finest fur, is more scattered on the sides of the mountains in America like that of woods, about the sixty-eighth degree of latitude, and it is said to be found as far south as New-England. Particular races of Martens, distinguished by the fineness and dark colours of their fur, appear to inhabit certain rocky districts. The rocky and mountainous, but woody district of the Nipigon, on the north side of Lake Superior, has long been noted for its black and valuable marten-skins.’

The same author gives the length of the head and body as from eighteen to twenty inches, and notices a remark of the natives that the fur loses all its lustre, and, consequently, much of its value, upon the falling of the first shower of rain for four or five weeks. He further states that this animal preyed and was an importunate and inconstant visitor to small libraries. A partridge’s head, with the feathers, is said to be the best bait for the log-traps in which it is taken. It does not reject carrion, and often destroys the hoards of meat and fish laid up by the natives, when they have accidentally left a crevice by which it can enter. When its retreat is cut off, it shews its teeth, sets up its hair,arches its back, and hisses like a cat. It will seize a dog by the nose and bite so hard, that unless the latter is well used to the combat, it escapes. Easily tamed, it soon becomes a master, but is not docile. The flesh is occasionally eaten but not prized by the Indians. The females are smaller than the males, go with young about six weeks, and produce from four to seven at a time about the end of April. According to Mr. Graham, this marten is sometimes troubled with epilepsy.

The importation of Pine Marten skins from Hudson’s Bay and Canada is great. Pennant relates that at one of the Company’s sales (in 1743) not fewer than 12,370 good skins, and 2360 damaged, were sold, and about the same time the French brought into the port of Rochelle from Canada no less than 30,955. Dr. Richardson states that upwards of one hundred thousand skins have long been collected annually in the fur countries.

The editor of the last edition of Pennant’s ‘British Zoology’ says that the length of a male which he saw in Suffork was nineteen inches, exclusive of the tail, which measured ten inches; the total length of the female the same, but the tail longer in proportion to the body. The breast of the latter was of a paler yellow, and the colour extended behind the ears.

Mr. Bell, after remarking that the colour of the fur is scarcely a tangible distinction, observes that different individuals of the Beech Marten vary quite as much in this respect as the Pine Marten and the Sable: the existence of fur on the toes, which has been introduced as a character of the Sable, probably depends, he observes, on climate; and is mentioned by Pennant as having been seen by him in the common Marten. ‘Never,’ says Mr. Bell, ‘having seen an undoubted whole specimen of the true Sable, I am unable to assert any of the differences given to our knowledge on the more important characters of the two animals; but I have found in the examination of numbers of the finest sable-skins, that the yellow patch on the throat had always an irregular outline, and that there were also small spots of the same kind scattered on the sides of the neck. This is a distribution of the colour which I have never observed on the common or Pine Marten. I offer the fact however, merely as one which, combined with other characters, may possibly aid in determining the question when we have fuller information on the subject.’

The probability seems to be that the Beech Marten, the Pine Marten, and the Sable do not offer sufficient differing characters to warrant their specific distinction.

The Pine Marten.

Asiatic Weasel.

Genus, Mydsus.

We select this form as an example of the Asiatic Mustelidae.

Generic Character.—Five toes on each foot, united up to the last phalanx by a very narrow membrane; claws proper for digging very large on the fore-feet, moderate on the hind-feet; tail rudimentary; pupill round; no external ear; four pectoral and two jugular mamme.

Dental formula:—Incisors, 6-6-6; canines, 1-1-1; false molars, 2-2; 3-3; flesh-cutting molars, 1-1; tubercular molars, 1-1; 1-1 = 34.

Example, Mydsus meliceps.
This is the *Teledu* of the Javanese east of Cheribon; *Seng-gong* of the Sundanese of the mountains districts from Cheribon to Bantam; *Mephitidae* of the inhabitants of Sumatra; *Mephitidae javanensis* of Bantam.

**Geographical Distribution.**—Dr. Horsfield states that this species presents a singular fact in its geographical disposition. It is, he says, exclusively confined to those mountains, which have an altitude more than 7000 feet above the level of the ocean, and on these it occurs with the same regularity as many plants. *The long-extended surface of Java,* continues Dr. Horsfield, *abounding with conical points which exceed this elevation, affords many places favourable for its resort. On ascending these mountains the traveller scarcely fails to meet with our animal, which, from its peculiarities, is universally known to the inhabitants of these elevated tracts; while those of the plains it is as strange as an animal to the country. In my visits to the mountainous districts I uniformly met with it, and, as far as the information of the natives can be relied on, it is found on all the mountains. It is, however, more abundant on those which, after reaching a certain elevation, consist of numerous connected horizontal ridges, than on those which terminate in a defined conical peak. Of the former description are the mountains Prahu and the Tengger hills, which are both distinctly indicated in Sir Stamford Raffles's map of Java: here I observed it in great abundance. It was less common on the mountain Gedê, south of Batavia; on the mountain Ungaran, south of Semarang; and on the mountain Ijen, at the farthest eastern extremity, but I traced its range through the whole island.*

**Teledu,**—Most of the species and ridges are cultivated for the production of wheat and European vegetables, and fruits, such as potatoes, cabbages, peaches, and strawberries in a deep vegetable mould, where the Teledus range, and in its search for food injures the plants and destroys the roots. It turns up the earth with its nose like a hog, and thus leaves vexatious traces of its nocturnal visits.

The dwelling of the animal is formed at a slight depth beneath the soil, under the roots of a large tree where it constructs a globular chamber in different soil, smooth and regular; and there is a subterranean approach to it about six feet long, the external entrance to which the animal conceals with twigs and dry leaves. Here it remains hidden during the day, and at night comes forth to seek the insects and their larvae, and common earth-worms, which are its food. They are said to live in pairs, and the female produces two or three young at a birth, according to the natives.

The felid matter, which is viscid, and which Dr. Horsfield was assured the animal could not propel beyond a distance of two feet, is very volatile, and consequently spreads to a great extent. The entire neighbourhood of a village is sometimes infected by the odour of an irritated Teledu; and it is so powerful in the immediate vicinity of the discharge as to produce syncope in some persons.

---

**Description.**—Agreed in size generally with the polecats of Europe and America. Eyes placed high in the head, resembling those of a hog, which animal is called to mind by the appearance of this species; eyelids rigid, well provided with minutely-bristled eyebrows; irides dark, pupil circular; ears nearly concealed by hair, but provided externally with an oblong conch surrounding the posterior part, and passing the lower extremity of the meatus auditorius, forming a small curve inward; no perceptible whiskers, a few long straggling hairs on the upper lip.

Fur composed of long, delicate, closely-arranged hairs, silky at the base, and forming a warm coat. Colour blackish-brown, more or less intense on every part of the body, except the crown of the head, a streak along the back, and the extremity of the tail, which are white, with a slight tinge of yellow, but in some individuals the streak is interrupted. The brown colour is generally lighter on the abdomen, and is subject to variations generally from greyish-brown to deep brown with a sooty tint; the last the most common. Tail scarcely half an inch long, the hairs projecting above an inch from the body. Limbs short and stout; feet plantigrade. Claws united at the base by a thick membrane enveloping this part as a sheath; those of the fore-feet nearly double the size of the hind-feet. Two glands of an oblong form, about an inch long and half an inch wide, near the extremity of the rectum, furnished with an excretory duct nearly half an inch long, which communicates with the intestine. Fluid secreted by the glands perfectly analogous in odour to that secreted by several species of *Mephitidae* in America, particularly that of *Mephitidae striata,* Fitch. Length of body and head, from extremity of nose to root of tail, one foot two inches and three quarters; of naked tail, half an inch; of tail, with hairy covering, two inches. (Horsf.)

---

**Teledu.** (Horsf.)

Dr. Horsfield describes the manners of this species as by no means ferocious, and states that, if taken young, it might, like the badger, be easily tamed. He kept one some time in confinement; it became gentle, and never
emitted its offensive smell. Dr. Horsfield carried it with him from Mount Prahu to Bleden, a village on the declivity of that hill, where the temperature was more moderate. It was tied to a small stake with which a string was being made, and moved about quietly, burrowing the ground with its snout and feet, as if searching for food, without the bystanders or making violent efforts to disengage itself. It ate voraciously of earth-worms (leumites) which were brought to it, and held one extremity of a worm in its claws while its teeth were employed in tearing the other. After it had eaten ten or twelve, it became drowsy, made a small groove in the earth, in which it placed its snout, and, having deliberately composed itself, soon slept soundly. (Zoological Researches in Java.)

African Weasels.

We select as an example, the Ferret, Mustela furo, Linnaeus; Viscera furo, Shaw.

Description.—Yellowish, different parts being more or less white, for the long fur is partly white and the short almost entirely yellow. Eyes pink. Length of head and body, fourteen inches; of the tail, five inches six lines.

This is Le Furet of the French.

Geographical Distribution.—Africa: domesticated in Europe.

The Ferret was well known to the ancients, and it appears that it was used by them much in the same manner as it is employed in the present day. Its use in Spain is noticed by Strabo, (III, p. 144, ed. Casaubon) and Pliny (Nat. Hist., viii, 56) speaks of its services, under the name of Viscera, in hunting rabbits by entering their burrows and lacerating them, so that they were taken when they bolted out.

Habits, &c.—Similar to those of the European Weasels, but more bloodthirsty. Capable of a certain degree of tameness, it seldom, if ever, becomes attached, and is a dangerous inmate unless properly secured. It has even been known to attack and cruelly lacerate an infant which had been left unguarded in its cradle, and with such ferocity that, after it had been driven away, the cries of the terrified child brought it from its hiding-place, eager to renew the attack.

This species, whose whiteness and red eyes may probably be the result of a long period of domestication, cannot bear cold, and should be kept warm to ensure its health, and condition. It is said to breed twice a year in a state of domestication, unless it devours its offspring, which it sometimes does, and then it has three litters. The gestation of the female continues six weeks, and she then produces generally six or seven young, sometimes nine. These are blind for a month, and at the end of two more are considered fit for service.

Ferrets should be kept in tubs or small boxes, and cleanliness is very essential to their health and strength. To enter them, they should, when the rabbits are half grown, be sent into the burrow with a line tied round them, and unmuzzled. When the ferret seizes a rabbit, the line should be gently pulled and the ferret drawn back, holding the rabbit in its mouth. This mode can only be practised where the burrows run comparatively straight and the tunnels narrow.

Ferrets should be fed before they are taken to the warrens, as they are filled with food they will not hunt, but burrows for hours. Before they are turned, they should be muzzled or coped, that being no name for human practices of sewing up ferrets.

The ferret is recommended as the best method of catching a piece of soft string round the neck; one piece round the head, and leave one piece over, piece round the under jaw, pass it under the teeth then round over the upper jaw, and there tie it, leaving the ends long. The mouth will thus be kept closed. Then bring the four ends together, and tie them in one knot on the top of the head; this makes all safe. No pain is inflicted apparently by this operation, for the ferret thus coped hunts as eagerly as if it were unmuzzled.

Daniel, in his Rural Sports, thus describes the method of catching. "The ferret is coped or muzzled, and a small bell tied round its neck; and after the holes are as silently as possible covered with purse-nets, called Plans, the ferret should be put in the windward side of the burrows, where the person should also place himself, and observe the utmost silence, otherwise the rabbits will retreat to their lower earths and be scratched to death before they will bolt. Hay nets are however chiefly used by experienced warrers, who are both to turn ferrets into burrows, which invariably give the rabbits a dislike to them. The mode of using these hay nets is then described.

AMERICAN WEASELS.

Genus Mephitis.

Generic Character.—Body elongated, arched; toes separated and armed with long claws, the anterior proper for burrowing. Tail long and very bushy, or entirely null. Anal glands secreting a foul odour.

Dental formula:—Incisors, 6; canines, 1;—1; molars, 1; 3-3. 5-3 = 32.

M. F. Cuvier gives the above cut as the dentition of Mephitis and Mydax. The dental formula is that given by Lesson for Mephitis. The feter of the species of Mephitis has obtained for them the names of Petes myas, Enfons de Diable, and Stinking or Stifling Weasels. M. Lesson observes that a great number of these American Mephistes have been de

The Ferret.
scribed, but the imperfect accounts of voyagers render the
arrangement unsatisfactory. He notices the following:
Mephitis americana; Meph. triangulata; Meph. cheniens;
Meph. chihuah; the Chiche; Meph. quinquis, and Meph.
interrapa. Dr. Horstfield gives the following representa-
tion of the profile of front teeth of Mephitis dimidiatata
of Fischer, the Chiche of Buffon.

![Profile of Mephitis dimidiatata](image)

**We select as an example the Mephitis americana, var.
hudsonia, the Hudson's Bay Skunk.**

**Description.** — The following accurate description is
from the pen of Dr. Richardson. 'The Skunk is low on
its legs, with a broad fleshy body, wide forehead, and the
general aspect rather of a Wolverine than of a Marten;
eyes small; ears short and round. A narrow white nasal
line runs from the tip of the nose to the occiput, where
it dilates into a broad white mark. It is again narrowed,
and continues so until it passes the shoulders. When it
forks, the branches running along the sides, and becoming
much broader as they recede from each other. They ap-
proach posteriorly, and unite on the rump, becoming at
the same time narrower. In some few specimens the white
stripes do not unite behind, but disappear on the flanks.
The black dorsal space included by the stripes is egg-
shaped, the narrow end of which is towards the shoulders.
The sides of the head and all the under parts are black.
The hair on the body is long. The tail is covered with
very long hair, and has generally two broad longitudinal
white stripes above on a black ground. Sometimes the
colours of the tail are irregularly mixed. Its under sur-
f ace is black. The claws on the fore-feet are very strong
and long, being fitted for digging, and very unlike those
of Martens; (Fissota Boreali-Americana.)

This is the Seeac of the Cree Indians.

**Geographical Distribution, Habits, &c.** — The author
last quoted states that the Skunk is not an uncommon ani-
mal in the district it inhabits, which does not, he believes,
extend to the north of lat. 56° or 57°. It is found in the
rocky parts of the country, but is still more fre-
quently in the clumps of wood skirting the sandy plains of
the Saskatchewan. Dr. Richardson had not been able to
ascertain the southern range of this variety of Skunk; and
he adds, that judging from Kalm's description, there ap-
pears to be a different one in Canada.

The Skunk lays itself up in a hole for the winter, seldom
going abroad at that season, and then for a short distance
only. Mice and frogs in summer are its principal prey.
Lawson says, 'Voles or Skunks in America are
different from those in Europe. They are thicker and
of a great many colours; not all alike, but each differing
from another in a peculiar colour. They smell like a
fox, but ten times stronger. When a dog encounters
them they pise upon him, and he will not be sweet again in
a fortnight or more. The Indians love to eat their flesh,
which has no manner of ill smell, when the bladder is out.
I know no use their fur are put to. They are easily brought
up tame.' Professor Kalm was almost suffocated by one
that was chased into a house where he slept: the very
cattle bellowed through distress at the stench. Another
that was killed by a maid-servant in a cellar so over-
powered her that she lay ill several days: the provisions
in the place were so tainted that the owner was obliged
to throw them away. Catesby says, 'When one of them is
attacked by a dog, to appear formidable it so changes its
usual form, by bristling up its hair, and contracting its length
into a round form, that it makes a very terrible appearance.
This menacing behaviour however, insufficient to deter its
enemy, is seconded by a repulse far more prevailing: for
some secret duct, it emits such fetid effluviums, that
the atmosphere for a large space round shall be so infected
with them, that men and other animals are impatient till
they are quit of it. The stench is insupportable to some
dogs, and necessitates them to let their game escape;
others, by thrusting their noses into the earth, renew their
attacks till they have killed it, but rarely care to have more
do with such noisome game, which, for four or five hours,
disappear from them. The Indians notwithstanding esteem
their flesh a dainty; of which I have eaten, and found it
well tasted. I have known them brought up young, made
domestic, and prove tame and very active, without exercis-
ing that faculty, which fear and self-preservation perhaps
only prompts them to. They hide themselves in hollow
trees and rocks, and are found in most of the Northern
Continent of America. Their food is insects and wild
fruit.' (Carol. I.) Dr. Richardson states that the noisome
fluid which it discharges is of a deep-yellow colour, and
contained in a small bag placed at the root of the tail. It
is, he says, one of the most powerful stenches in nature,
and so durable that the spot where a Skunk has been killed
will retain the taint for many days. He quotes Graham
for the fact that several Indians lost their eye-sight in con-
sequence of inflammation produced by this fluid having
been thrown into them by the animal, which has the power
of ejecting it to the distance of upwards of four feet.
'I have known,' says Dr. Richardson in continuation, 'a dead
Skunk, thrown over the stockade of a trading post, pro-
duce instant nausea in several women in a house with
closed doors upwards of a hundred yards distant. The
odour has some resemblance to that of garlic, although
much more disagreeable. One may however soon become
familiarized with it; for, notwithstanding the disgust it
causes at first, I have managed to skin a couple of
recent specimens by recouring to the task at intervals.
When care is taken not to soil the carcasse with any of
the strong-smelling fluid, the meat is considered by the
natives to be excellent food.'

![The Skunk](image)
WEAVER BIRDS. _Ploceina_, a subfamily of Fringillidae, in which article and in _Vidua_ the opinion of zoologists as to their place in the system was fully discussed. The genus _Ploceus_ of the Weaver birds is thus defined by Mr. Swainson.

Size small. Bill conic, but with the culmen slightly bent, and the tip entire. Under mandible less thick than the upper. Claws large, very long. Wings pointed.

Vol. XXVII.—2
The birds in question are said to construct their nests in one clump and under one roof or cover, each nest having a separate entrance on the under side, but not communica-
ing with the nest next to it from within. A space of ten feet in diameter is stated to be sometimes reached by these aggregated sylvan dwellings comprising a bird-popula-
tion of some hundreds.

Paterson thus describes the operations of these social
winged citizens:— The industry of these birds seems
almost equal to that of the bee. Throughout the day they
appear busily employed in carrying a fine species of grass,
which is the principal material they employ for the pur-
pose of erecting this extraordinary work, as well as for
additions and repairs. Though my short stay in the
country was not sufficient to satisfy me by ocular proof
that they added to their nests as they annually increased
in their numbers, still, from the many trees which I have
seen borne down by the weight, and others that I have
seen with their boughs completely covered over, it would
appear that this is really the case.

When the tree that is
the support of this serial city is obliged to give way to
the increase of weight, it is obvious that they are no longer
protected, and are under the necessity of building in other
trees. One of these deserted nests I had the curiosity to
break down, to inform myself of the internal structure of
it, and found it equally ingenious with that of the exter-
nal. There are many entrances, each of which forms a regular
street, with nests on both sides, at about two inches' dis-
tance from each other. The grass with which they build
is called the Boshman's grass, and I believe the seed of it
to be their principal food, though, on examining their nests,
I found the wings and legs of different insects. From
every appearance, the nest which I dissected had been in-
habited for many years, and some parts were much more
complete than others. This therefore I conceive to amount nearly to a proof that the animals added to it at different times, as they found it necessary, from the increase of their family, or rather of the nation and community.'

One of these bird-towns is also figured in Mr. Wood's 'Zoography,' and we here endeavour to present a sketch of part of the plate.

Another weaver's nest, that of *Ploceus icterocephalus*, Sw., brought together with the male, female, and eggs, from South Africa to Mr. Swainson, is thus described by him:—'The nest is somewhat kidney-shaped, seven inches long, and four and a half broad: it is attached to a very slender branch, from which there are four other young shoots, which serve as so many holds for its support, and to which it is firmly fixed by bendings of strong grass leaves. The whole is very compactly made of the same materials, interlaced most ingeniously, and far more firmly than what is seen in the chaffinch or other of our most skilful builders: the lining is the heads or panicles of the grasses, thus uniting softness and coolness, the latter being an obvious advantage in so sultry a climate. The aperture is lateral, near, but not upon, the top, so that it serves the purpose of a window to the inmates, who are sheltered overhead by the convex top of the nest. There is something very ingenious in the construction of this opening, which is not, as it first appears, round, but semicircular, the arch being bound round with a stronger band than usual, and the plane or base, much stronger, and composed of straight pieces of the stalks of grass, evidently for the purpose of giving to that part upon which the birds perched greater strength and substance.'

Mr. Swainson, after remarking that lateral openings to the nests of African birds are very common, goes on to observe that the rains of South Africa and of tropical America are, perhaps, equally violent while they continue; but then the small leaved and scanty foliage of the trees in the former locality leave the nests of such birds as are upon them much more exposed to these torrents than are the nests of the birds of Brazil, where the foliage is particularly thick and broad; and he inquires whether this may not be one of the causes, at least, why nature has so especially taught the African birds to construct their nests in the manner alluded to? Snakes, he observes, are equally common in both regions, yet, with the exception of the Hangnests, and a very few others, as *Synallaxis garrulus* [**Synallaxis**], and *Donacobius coeciferans*, &c., he declares that he is unacquainted with any other Brazilian birds which depart from the ordinary style of building.

Dr. Smith, in his *Zoology of South Africa*, a considerable portion of which he accurately observed with the eye of a philosophical zoologist, expresses his decided opinion that the fear of injury from small quadrupeds and snakes operates upon the birds of that country in their choice of trees overhanging pools of water as the localities for their nests. 'There can be no doubt,' says he, 'that parental affection dictates the choice. All the birds of South Africa are liable to have their nests robbed by small quadrupeds and snakes, and as no position is so likely to secure them against such misfortunes as those we have mentioned, they are doubtless selected under that conviction.'

Most deadly enemies do these same snakes appear to be to the South African birds, and the same distinguished author, in his elaborate account of the varieties of *Buc- phalus capensis*, *Boom-stange* of the colonists, which he does not consider poisonous for reasons which he states in his work, gives the following description, which, while it shows the natural dread of the bird affords a very interesting illustration with regard to the alleged fascination of serpents. 'The Boom-stange,' says Dr. Smith, 'is generally found upon trees, to which it resorts for the purpose of catching birds, upon which it delights to feed. The presence of a specimen in a tree is generally soon discovered by the birds of the neighbourhood, who collect around it, and fly to and fro, uttering the most piercing cries, until some one, more terror-struck than the rest, actually seizes its lips, and almost without resistance becomes a meal for its enemy. During such a proceeding the snake is generally observed with its head raised above ten or twelve inches above the branch round which its body and tail are entwined, with its mouth open and its neck inflated, as if anxiously endeavouring to increase the
tectorial, it would almost appear it was aware would sooner or later bring within its grasp some one of the feathered group. Whatever may be said in ridicule of fascination, it is nevertheless true that birds, and even quadrupeds, are, under certain circumstances, unable to retire from certain of their enemies; and, what is even more extraordinary, unable to resist the propensity to advance from a situation of actual safety into one of the most imminent danger. This I have often seen exemplified in the case of birds and snakes; and I have heard of instances equally curious, in which antelopes and other quadrupeds have been so bewildered by the sudden appearance of crocodiles, and by the primacies and contortions they practised, as to be unable to fly or even move from the spot, towards which they were approaching to seize them.

We now proceed to lay before our readers some of the species of this interesting group of birds.

_Ploceus spinolonas_, Vigors.

Description.—Upper part of the head gamboge-yellow slightly glossed with honey-yellow; sides of the head, chin, and a narrow line stretching from the latter to the breast, dark liver-brown verging on black; sides of the neck immediately behind the ear coverts, breast, belly, vent, and under tail coverts, light gamboge-yellow, lateral fringes of the breast tinted with saffron-yellow. Lower part of the back and sides of the neck, interseparans, and back, liver-brown, each feather broadly tipt with lemon-yellow; rump yellow, blotched with liver-brown. Lesser wing coverts, primary and secondary quill coverts, primary and secondary coverts of tail, and a saddle at the base of the lower tail feathers, light chocolate-brown, the primaries and their coverts edged externally with king's-yellow, the others tipt and edged on both vanes with the same colour. Tail light greenish-brown, the feathers faintly margined externally with king's-yellow, and internally with primrose-yellow. Bill brownish-black. Eyes deep vermilion-red. Feet flesh-coloured, tinted with brown; claws pale horn-colour. Total length from point of bill to tip of tail seven inches. (Smith.)

The above is the description of the _male_; nothing, according to Dr. Smith, is known of the _female_.

This is the _Ploceus stictonotus_ of Smith (South African Quarterly Journal); and _Ploceus flaviceps_ of Swainson (Birds of West Africa).

Locality and Habits.—Dr. Smith states that this Weaver inhabits the districts bordering on the south-east coast of Africa; but he had not seen nor heard of its being found to the westward of Kafirland. It is rare, and generally seen on the banks of rivers. From the trees that overhang the waters these birds suspend their nests of a somewhat kidney form, composed of blades of grass so closely interwoven as to form a complete protection against the weather. Dr. Smith, who gives this account, states that the female lays three or four eggs of a delicate greenish-blue, and about the size of those of the Common Sparrow. Mr. Swainson says that his specimen was received from Senegal.

Of _Ploceus capensis_, Smith, (P. abysinnicus, Cuv.), Dr. Smith states that it is diffused over the more southerly districts of South Africa, and that flocks of from ten to forty individuals are often to be seen on or near the edges of the larger rivers and along the banks of streams. From them, when seized by the hands they suspend, he says, their nests; five or six of which are sometimes attached to a single branch. These nests are somewhat kidney-shaped, with the entrance towards the upper end, and directed downwards. Dr. Smith adds that they take up the nearest pools of water are invariably preferred, and the twigs which approach nearest the water are commonly best supplied with nests.

The head-quarters of _Ploceus subauratus_ and _Ploceus ocularis_ be looked for, according to Dr. Smith, to the northward of the Tropic of Capricorn: at least is scantly comprised of any species to the southward of it, in his opinion, warrant such an inference. During a residence of fourteen years in South Africa, he only met with four specimens of _Ploceus ocularis_ and _Ploceus subauratus_. The specimens of _subauratus_ previously himself were all killed in the neighbourhood of Algoa Bay, and those contained in the collections submitted to his inspection were either obtained in the same locality or more to the eastward.

Dr. Smith says that the females of the individuals of _Ploceus ocularis_ any disposition to congregate—at least he rarely found more than the male and his female associated together, and these were generally discovered in retired situations, well supplied with trees, and the nests of these birds are constructed with a line of delicate fibres of bark closely interwoven, so fashioned as to present, when complete, the form of a retort. The three blush-white eggs are sparingly spotted with dusky brown—the large extremity having the large extremity having the Occasionally numerous spots upon other eggs. The male and male and female sit alternately, and, while so occupied, are so devoted to their duty, that they may with the greatest ease be taken in the nest alive.

_Phitelerus lepidus_, Smith.

Description.—Figure rather slender; bill more compressed than in _Euplectes_; culmen slightly arched from the base; commissure sinuated; legs and toes strong; tarsi in front covered by transverse plates, the margins of which are distinctly defined; outer and inner toes nearly of equal length; claws pointed and much curved, the hinder one not so long as in the typical species of _Euplectes_; wings, when folded, reaching to about the middle of the tail. First or spurious quill-feather very short, scarcely discernible; second, third, and fourth, nearly of equal length; and the longest; extremity of the tail slightly rounded. (Smith.)

Male.—Dr. Smith describes the top of the head, the neck, and the back as of a drab-brown; back and sides of the neck and interscapulars amber-brown; edging of these feathers with pale isabella colour; chin and a stripe at the base of the bill which terminates on a line with the eye, black. Wings and tail light amber-brown; tertiary quill feathers broadly edged and tipt with isabella, of which colour are the tail-feathers, also, at the base. Head, under part of the neck, breast and belly pale isabella; flanks pale rusty brown; on the front of each thigh a deep black stripe; the feathers margined with yellowish-white. Bill and legs a pale horn-colour, the former slightly curved and black brown. Eyes dark reddish-brown.

Female.—Differing from the male in having the feathers of the back and sides of the neck and interscapulars light brown instead of amber-brown.

Young.—Head streaked with brown, the patch in front of the thighs consisting of the back of the larger species, black spots. No appearance of black on the chin or at the base of the bill.

Length from the bill to the point of the tail, 4 inches 8 lines.

This is the _Loxia socius_ of Latham; _Ploceus socius_ of Cuv.; _Philetairus lepidus_ of Smith; and _Euplectes lepidus_ of Swainson.

Geographical Distribution and Habits.—Dr. Smith states that the banks of the Orange River appear to constitute the southern limit of the range of this species, which was only obtained in great abundance in the districts round Latakoo far from water. ‘The most striking peculiarity,’ adds Dr. Smith, ‘observed in this species is the extraordinary
nary manner in which a number of individuals associate, and build their nests under a common roof. When a nesting place has been selected, and the operation of building

mediately proceed conjointly to construct the general covering which interests them all; that being accomplished, each pair begins to form their own nest, which, like the roof, they construct of coarse grass; these are placed side by side against the under surface of the general covering, and by the time they are all completed, the lower surface of the mass exhibits an appearance of an even horizontal surface, freely perforated by small circular openings. They never use the same nests a second time, though they continue for many years attached to the same roof. With the return of the breeding season, fresh nests are formed upon the lower surface of those of the preceding year, which then form an addition to the general covering. In this manner they proceed year after year, adding to the mass, till at last the weight often becomes such as to cause the destruction of its support: upon which a new building is selected. They appear to prefer constructing these nests upon large and lofty trees, but where such do not occur, they will even condescend to form them upon the lea\vs of the arborescent aloe (Aloe arborescens), as occasionally happens towards the Orange River. The commencement of the roof is firmly interwoven with the branches of the trees to which it is intended to be suspended; and often a great part of a principal branch is actually included within its substance. Each female lays from three to four eggs, which are of a bluish-white colour, and freely mottled towards the large end with small brown dots. When once this species has attained maturity, it never afterwards exhibits any change in respect to colours. The male has no summer tints which he throws aside in winter, as is the case in Euplectes. Seeds, and occasionally small insects, constitute the food.

Euplectes talha, Smith.
Description.—Male; summer plumage. Crown of head, back, upper and under tail-coverts, vent, and a narrow oblique stripe on each side of the breast immediately in front of the shoulders, bright yellow shoulders, quill-feathers, and tail, grey-brown; shoulder feathers, and the outer vanes of the quill-feathers, faintly edged with dirty-white; sides of shoulders pale creamy-yellow varying on the white; thighs pale yellow freckled with brown. Space in front of the eyes, sides of the head, stripe on each side of back adjoining the bases of the wings and all the under parts of the body as far as the vent, deep brownish-black. Head light umber-brown, the lower mandible lightest. Feet and claws yellowish-brown; eyes brown.

Male; winter plumage. Above, pale yellowish-brown; head, neck, and interscapulars freely dashed with longitudinal brownish-black stripes or blotches, and the back and upper tail coats with faint narrow stripes of the same colour. Eye-brows yellowish-white; ear coverts pale rusty brown; under parts of body greyish-white, throat and breast tinged with siena-yellow, and these as well as the flanks narrowly streaked brown. Bill, particularly the lower mandible, lighter than in summer.

Adult Female.—Coloured in summer and winter nearly the same as the male in winter. (Smith.)

Geographical Distribution and Habits.—Dr. Smith states this species does not appear to extend south of 26°, at least he discovered no individuals before he reached that latitude. The natives more to the southward seemed to be unacquainted with the bird. In the districts to the north of 26°, however, it was common, and large flocks were often observed among the trees near the banks of rivers. Dr. Smith further remarks that though they were generally among trees at the time he passed through the country, he was informed that they leave them at the commencement of the breeding season, for the reeds which skirt the rivers here and there, and from which they suspend their nests. They are, he states, very destructive to gardens, like Euplectes oryz, in the summer, and the natives are obliged to watch their crops to prevent them from being devoured by one or other of their species.

Dr. Smith enumerates the following species of Euplectes as inhabitants of South Africa:—oryz (Loxia oryz, Linn.), capensis (Loxia capensis, Linn.), and taha.

Plocepasser mahali (Agrophilus, Sw.).

Description.—For head, top of the head, nape, lores, and stripe from the angles of the mouth to the top of the neck, liver-brown; sides of the head and ear-coverts broccolli-brown, tinged with yellowish-brown; eye-brows broad, dusky white. Upper and lateral parts of the neck, interscapulars, back, and lesser wing-coverts intermediate between brocstioli and wood brown; last row of the lesser wing-coverts broadly tipped with pale cream-yellow; primary and secondary quill-coverts light liver-brown, the former narrowly, the latter broadly margined with rusty white; rump and upper tail-coverts yellowish white; tail-feathers liver-brown, tipped and narrowly edged externally with rusty white. Chin, throat, vent, under tail-coverts, and thighs dusky white; breast, belly, and flanks, dirty cream-yellow, inclining to pale wood-brown. Bill dull yellowish-brown, shaded with brownish red; legs, toes, and claws same colour. Eyes deep brownish orange. Length from point of bill to tip of tail 6 inches 64 lines.

Female very similar to male in colour. (Smith.)

Geographical Distribution and Habits.—Dr. Smith first saw this bird upon a tree on one of the tributaries to the Orange River. The nests in figure and texture had many of the characters of those of Ploceus, but resembled those of some of the South African Pyrgites in the manner in which they were armed. The walls of each nest were entirely composed of stalks of grass, the thickest extremities of which were so placed as to protrude externally for several inches beyond the compact structure destined to contain the eggs. Thus each nest appeared armed with numerous projecting spines, and bore considerable resemblance to the body of a porcupine with its spines partially erected. Several of the Pyrgites, Dr. Smith remarks, arm their nests after the same fashion; but they select for the purpose the delicate twigs of shrubs or brushwood, instead of stalks of grass. The object of both is, he observes, to offer an obstacle to the advance of snakes towards the eggs and young. Dr. Smith adds that a solitary specimen of Plocepasser is seldom seen, and that the bird is disposed to congregate. He met with small, and even occasionally with large flocks, as far north as the Tropic of Capricorn. Twenty or thirty nests were to be seen upon one tree. Seeds and insects are the food, and, in search of these, the bird passes much time upon the ground. If disturbed when thus feeding, the flock move away in a body to a neighbouring tree, where they remain till they are satisfied that they may return to their employment.
Smith, and Plcpepasser supercinlus (Agrotillus super-
citius, Sw.).

Textor erythrorhynchus.

Description.—Head, upper and under parts, the last
half of each primary quill, all the secondary quills, and
the tail, blackish-brown; first half of each primary quill
white, outer vanes of a few of those nearest to the second-
aries margined with the same colour almost to their
points. Bill light yellowish-red, clouded with shades of
purple-red; legs and toes yellowish-brown, the former
stinted with yellowish-red; claws livid-umber-brown. Eyes
dark brown.

Female.—The brown tint more distinct than in the
male; in other respects very similar in colour.

Young.—Dusky liver-brown; feathers of breast and
belly broadly margined with white. Slight indications
of such white margins are often to be observed upon the
feathers of the sides and body in adults. (Smith.)

avocation, and pursue a course similar to that just
described, provided the like circumstances recur. We never
found this bird attaching itself to any quadruped but
the buffalo, nor did we ever find the latter with any
other attendants, though we found in the country in which
both exist two other birds in the habit of feeding upon pa-
ristical animals, namely Buphaga Africana and erythrho-
rhynchus. These restricted their visits exclusively to the
roosters. (* Art. 256.

WEAVING. If we take the term 'weaving' in
its broadest sense, as applying to the process of combing
longitudinal threads into a superficial fabric, it will have
relation to the whole series of textile manufactures; not
only to those which are prepared in the loom, but net-
work, lace-work, and hosiery. We shall endeavour
therefore in the present article to complete the details
of manufacturing many textile fabrics which have been par-
tially described in former articles; and as, to effect this,
the sort of class distinction will be desirable, worthy stories
after briefly noticing the state and progress of weaving
among the antients, to proceed thus—Plain Weaving;
Pattern Weaving; Double Weaving; Cross Weaving;
Chain Weaving; Pile Weaving; Power Weaving.

From many passages in the Bible, and from the general
character of dress, it is apparent that woven fabrics were
worn in very early times. In a state of society where
there was practised before spinning; that is, the combination
of reeds, strips of leather, or rude fibres into a material for
dress, by a process analogous to that of weaving, preceded
the practice of spinning yarn from a congeries of element-
aries.

Sir J. G. Wilkinson, in his work on Egypt, (Man-
ners and Customs of the Antient Egyptians), obse-
res, the Egyptians, from a most remote era, were cele-
bated for the manufacture of fabrics, and the produce
of their looms was exported to, and eagerly purchased by,
foreign nations. The fine linen and embroidered work, the yarn and woollen stuffs, of the
upper and lower country, are frequently mentioned,
and were highly esteemed. The same authority tells
that the looms, found depicted on the tombs at Thebes,
are of an exceedingly rude construction; but he does not
think that this circumstance militates against the prod-
uction of fine fabrics, since it is known at the present
day that the Hindues produces excellent materials on
the rude loom. In a specimen of mummy-cloth, examined by Mr.
Thompson, the texture was close and firm, yet elastic;
the yarn of both warp and weft was remarkably even and well
spun; the web was single, while the warp-yarn consisted
of many threads. The weaver, or weavers, was unable,
in that as well as in other specimens, that the number
of threads to an inch in the warp uniformly exceeded that
in the weft, a difference not commonly observable in Euro-
pesian fabrics. Mr. Thompson is led to conclude that
being brought to England by Salt and Belzoni, and found that
the 'selvages' were well made, that striped goods similar
to modern ginghams were often made by the Egyptians,
and that indigo was one of the dyes. Wilkinson
gives copies from some of the pictures at Thebes, Beni
Hassan, and Eileithyas, representing weavers at their
looms; in one instance the loom appears to be horizontal;
while in another it is vertical, with the weft driven up-
wards; and from representations of five different sorts of
weaving the writer appears to have evidence that they were generally about
half a yard in length.

Mr. Yates (art. 'Tela,' Smith's Dictionary of Greek and
Roman Antiquities) has collected most of the authentic
details respecting the art of weaving among the Greeks
and Romans, from which we have extracted the
illustrations.

Weaving was carried on as a distinct trade in the larger
towns; but every considerable private establishment had
also a loom at which the females of the family were em-
ployed; the weaving being carried on by females, while the superintendent rested with the mistress
and her daughters. In large houses a particular room was
set apart for this occupation. The Greeks and Romans
differed from the Egyptians in this, that the weaving
was among the ladies, and performed by women;
while among the Greeks and Romans it was a female em-
ployment. The shawls furnished to the temples were
woven by women, in some cases attached to the more opulent temples, but in other cases independent of them; thus the sixteen women who lived together in a building destined to their use at Olympia, wove a new shawl every five years, to be displayed at the games which were then celebrated in honour of Hera, and to be preserved in her temple. Plato mentions one of the most important differences between the warp and the weft, viz. that the threads of the former are strong and firm in consequence of being more twisted in spinning; whilst those of the latter are comparatively soft and yielding; a comparison which is strictly applicable at the present day. Mr. Yates remarks that the parallelism or interlace of the loops in the warp is a feature to show the analogy between the ancient Greek loom and the modern so-called hand-loom; both having the warp-threads vertical; whereas in the improved looms of modern times the warp is always horizontal. The Greeks evidently understood much of what is now termed "mounting a loom," that is, arranging strings in such a manner as to separate the warp-thread into two or more groups, between which the weft may be introduced: the leafl (πήρος) being one such string, and a hole or the even length termed a θρόνος; these strings, according as it contained two, three, or more groups of strings, or, as we should now say, leaves or heddles. After the weft was thrown, it was driven up, either by a kind of bat, called a σπάθα, or by a kind of eel, both of which appear to have been combined in the "batten" or "lay" of the modern loom. The "check" produced by having different coloured warp threads, and "stripes," formed of multicoloured wefts, were known to the Greeks and Romans; as were likewise numerous kinds of fancy weaving derived from those two combinations. Mr. Yates endeavours with this remark: "As far as we can form a judgment from the language and descriptions of antient authors, the productions of the loom appear to have fallen in antient times very little, if at all, below the beauty and variety of the fabrics produced in those countries and those times, so far as it differs from modern European weaving. The Hindoo weaver takes his station under the trees, where he stretches his warp-thread between two bamboo rollers, which are fastened to the turf by wooden pins. He digs a hole in the earth large enough, stands up to his lesls, in a sitting posture; and then, suspending to a branch of a tree the eords which are intended to cause the raising and depressing of the warp-threads, he fixes underneath two loops for his toes, by which he produces a substitute for true bobbins. He then sets up a frame as a stool or table, completes his simple arrangements. With such rude apparatus as this is the process of weaving conducted in nearly all the villages throughout India. We will now compare these methods with the mode of procedure in modern Europe.

Plain Weaving.—By the term "plain weaving" we mean the weaving of all varieties of textile manufacture, whether of silk, cotton, woolen, or linen, in which the warp threads interlace uniformly among the warp threads without producing twills, checks, stripes, springs, or any variety of figures. Cilician, Irish linen, and plain silk are good representatives of this kind of weaving. If we examine any of these, we shall find that the cross threads pass alternately over and under the warp threads one thread passing over and under two other threads at one. In the language of weavers, the long threads are called warp, twist, caine, or organzine; while the cross threads are called weft, woof, shoot, or tram. Twist is the general term applied to the kind of yarn employed in the warp; organzine is that for silk, and some other of the terms have in like manner only partial application; if therefore we speak simply of warp and weft, we shall avoid ambiguity, and be sufficiently correct for the object in view. The warp is always affixed to the loom on the weaving machine; while the weft is contained in the shuttle, a small boat-like instrument. The winding of the weft on the spindle which runs through the shuttle is a simple matter; but the arrangement of the warp in the loom is very important, and must be understood before we enter into the process of weaving.

The first operation consists in laying the requisite number of threads together to form the width of the cloth; this is called warping. Supposing there to be 1000 threads in

Fig. 1.

the width of a piece of cloth; then the yarn, wound on the bobbins as it leaves the hand of the spinner, must be so unwound and laid out as to form 1000 ends, constituting when laid parallel the warp of the intended cloth. The antient method was to draw out the warp from the bobbins at full length in an open field; and this is still practised in India and China; but the climate of Europe is too uncertain for such a method, and hence the warping-frame was devised. This is a large wooden frame fixed up vertically against a wall, the upright sides being pierced with holes to receive wooden pins, which project sufficiently to receive the end or group of yarns. The warper, having placed the bobbins of warp on a recent frame, ties the ends of all the threads together, and attaches them to one of the pins; then gathering all the threads in his hand into one bundle, and permitting them to slip through the fingers, he sets the loom into motion, where he passes the yarns over the fixed pins. He walks from end to end of the frame, attaching the clew of yarns to the pins each time, until he has unwound from the bobbins enough yarn to form the warp. But this method, although still followed in some places, is too laborious. The warping-mill, a much more convenient piece of apparatus. The bobbins are placed in a frame E (Fig. 1). The warper, sitting at A, rotates the vertical reel, or cylinder B, by means of the wheel C and the rope D. The yarns from all the bobbins, collected together in a group at F, pass through a sliding piece, which, through the intervention of the eord G and the revolving shaft H, rises and falls. By this arrangement it is easy to see that when the handle is turned by the warper, the clews become wound spirally on the reel. The diameter of the reel is so regulated, that when the spiral equals the intended length of the warp, the clews of yarns is twisted round pins p, q, r, s, and then by a reverse motion of the handle is wound spirally down again; and so on up and down alternately until the grouped clews of yarns constitute a sufficient number for the width of the warp. Certain minor adjustments are at the same time made. The modern warping-machines we have to mention when we come to 'power-weaving.' When the warp is completed on the warping-mill, the warper takes it off and winds it on a stick into a bale, preparatory to the process of beaming, or winding it on the beam of the loom. The threads, in this latter process, are wound as evenly as possible on the beam; a separator, ravel, or comb being used to lay them parallel, and to spread them out to about the intended width of the cloth. Arrangements are then made for dressing, or attaching the warp-threads individually to certain mechanism of the loom. This we may illustrate by Fig. 2, representing the common loom in its simplest state. The yarn-beam is at B, with the machine revolving, and allowing the threads to be drawn out in a horizontal layer B. At F are two leaves of heddles or reeds, each leaf consisting of a number of strings ranged vertically, attached at bottom to
two treads H H, and at top to a cross-bar F. At about the middle of every heddle or string is a loop or eye, through which the warp-yarns are drawn, one through each eye; and the passing of the yarns through these loops constitutes the process of dressing. Half of the warp-yarns, that is, every alternate yarn, pass through the loops in one leaf of heddles, and the other half through the other leaf; and so the two leaves are so connected by pulleys as to cause one to rise when the other sinks, the warp becomes divided into two portions, one above the other, near the anterior end of the loom. The weaver sits at G, drives the shuttle by means of the handle I, and draws up every successive weft-thread by the batten, lay, or lathe, E, suspended from F. The succession of movements must be noticed somewhat more in detail in the next paragraph.

There are three movements attending every thread of weft which the weaver throws across the warp. In the first place he presses down one of the two treads, by which one of the two halves of the warp is depressed, thereby forming a kind of opening called the ‘shed.’ Into this shed, at the second movement, he throws the shuttle containing the weft-thread, with sufficient force to drive it across the whole web. Then, at the third movement, he grasps the batten, which is a kind of frame carrying at its lower edge a comb-like piece having as many teeth as there are threads in the warp, and with this he drives up the thread of weft close to those previously thrown. One thread of weft is thus completed, and the weaver proceeds to throw another in a similar way, but in a reverse order, that is, by depressing the left tread instead of the right, and by throwing the shuttle from left to right, instead of from right to left. In the commonest mode of weaving the shuttle is thrown by both hands alternately; but about a century ago John Kay invented the ‘fly-shuttle,’ in which a string and handle are so placed that the weaver can work both shuttles with one hand. The fly-shuttle is illustrated in Cut 3, while Fig. 3 will show more clearly the mode in which the weft is wound round.

The spindle or pin of the shuttle, and the most improved arrangement for driving the shuttle into the open shed of the web. The spindle of the shuttle contains enough weft for several shots or throws; the shuttle travels along, and forming the ‘selvage’ of the cloth when the shuttle returns in the opposite direction.

In cotton and some other fabrics, the warp-yarns must be ‘dressed’ as the weaver proceeds, that is, rubbed over with some kind of vegetable substance, such as lime, for the purpose of giving them tenacity, of diminishing friction by smoothing down the little hairy filaments of the yarn, and of imparting a smoothness or gloss. In hand-weaving, the weaver suspends his operations from time to time, in order to apply dressing to the warp, first applying a kind of comb to the warp, to clear away knots and burrs; then lays on the paste with a brush; and lastly dries the paste by a current of air excited by a large flame. The more modern and complete ‘dressing-machine’ we shall have to notice in connection with ‘power-weaving.’

In weaving plain silks, calicoes, and other webs of moderate width, there are two leaves of heddles and two threads of the warp thrown into two parcels. In weaving broader webs, such as floor-cloth canvases, the heddles and treads are equally simple, but more power and dexterity are necessary in throwing the shuttle, since the width of the web is sometimes as much as eight yards. In weaving very fine webs such as lawn, muslin, damask, where there would be a waste of power and of time if only one shuttle were thrown across a distance of two or three inches at each movement; and there has consequently been devised a kind of loom called the ‘engine-loom,’ in which several shuttles are thrown across at the same time, and which will save much time.

Patterns, or designs, which can be worked into the warp or filling of the web can also be produced by dressing them on the weft. The weaver must, of course, keep them in mind, and be prepared to repeat them when they come up. But this is not the case with a power-loom, when many patterns are at the weaver’s command, in case he is not experienced enough to be able to remember them all. In weaving, therefore, patterns are not so much the province of the weaver as of the manufacturer.

In the first place we may take the case in which all the threads of the warp are the same colour, and all those of the weft another colour; this produces the peculiar effect called shot patterns, but involves no new arrangements as to weaving. Next come the two varieties known respectively as stripes and checks. A stripe is a pattern in which two parallel lines run across the web; a check is an alternation of rectangles like a chess-board, or more properly like the varieties of Scotch plaid. The production of a stripe depends either upon the warp or weaver; the production of a check depends upon both. The stripes are of the same colour, and extend lengthwise of the cloth, then the weaver so disposes the threads of his warp that the two colours shall succeed each other at regular intervals; but if the stripes are of the same colour, but of different quality as to fineness, then the warp and weft are two qualities of warp in alternate succession. If the stripes extend across the cloth, the weaver arranges his threads as for plain weaving; but the weaver uses two or more shuttles, carrying two or more differently-coloured wefts, and throws the shuttles in regular intervals, so that the alternating of the long stripes with the cross-stripes produces the effect of a design, the terms of which depends on the comparative width of the various stripes. The manner of using the combined shuttles is described under Check.

The next to be noticed is the production of the twill, a very extensively adopted variety of woven work, since it comprises satin, bombazene, kerseymere, and numerous other kinds. In the twill, the warp-threads do not pass over and under the warp-threads in regular succession; but pass over one and under two, over one and two, or over two and under one, according to whether the web, or one or two, or eight or ten according to the kind of twill. The effect of this is either of diagonal ribbed appearance, or

Vol. XXVII—2 A
the 'wrong' side of the cloth, and a smooth and glossy appearance on the other, according as the one thread is crossed above or below by the weft. Fig. 4 will assist our comprehension of this point. If we suppose the round dots to be sections of successive warp-threads and the white double line to be one thread of weft, we shall see that the second round of four under, over four, under four, over four, under, over four, and if the specimen were continued, we should see that these cycles of changes succeed each other in regular order. This arrangement furnishes the ‘twill’ for some particular varieties of cloth and has been produced in a kind of formation called diaper, dinty, dornock, damask, bombezen, satin, kersey, mere, &c.; each one having a certain order of succession in which the weft crosses the warp. (A few particulars will be found under Bombezen and Damask.)

Now in order to allow the weft to pass under four or more threads at once, some mechanism must be devised for elevating all those four at one movement, or of keeping them stationary while every fourth thread is depressed. If the weft always passed under the same four threads, no cloth would be produced, for naturally it would be made; but the groups of four passed under one weft-shoot are not the same as those crossed at the next following shoot. Hence more than two leaves of heddles are required, and more than two treadsles to work them. There must in number thus be a greater number of heddles than there are treadsles; each of which fifth warp-thread is attached; and to each of these leaves a treadle is appropriated; so that when one treadle is pressed down, the warp-threads become drawn out of the horizontal plane; when another treadle is depressed, the leaves of heddles, to which each of fifth warp-thread is attached, are depressed, and the hole pass for the weft is made. By various combinations among his five treadsles, he can produce many varieties of movement, which give rise to different kinds of twills.

When, instead of or in addition to a twill, the weaver has to produce sprigs, flowers, spots, or any kind of figure, a great increase of complexity occurs. The weft may pass over four and under one at one part of the width of the cloth; over two and under two at another; over one and under four at the other; according to which figure which may happen to occur at any particular part of the width of the cloth. Hence the order in which the warp-threads must be depressed or elevated varies continually, and the number of leaves of heddles would become so great that in a few days, it might be necessary to change the warp-threads, or to find some method of preventing the feet of the weaver from moving them. This difficulty gave rise to the invention of the draw-loom, in which strings are so arranged that a boy can draw down the requisite warp-threads preparatory to the movement of the shuttle. The draw-loom, from the immense number of its vertical and horizontal strings, is a very incomprehensible piece of apparatus to a stranger, whether seen actually at work or represented in an engraving; but its principle, example enough. The warp-threads pass through eyes or loops in vertical strings, each threading one string; and these strings are so grouped that the attendant boy, by pulling a handle, draws up all those warp-threads which are necessarily elevated for one particular shoot of weft; and when the order of succession is required, he pulls another handle. Hence it follows that the arrangement of the strings and handles must be preconcerted with especial reference to one particular pattern; and this is called ‘cording the loom.’ The draw-loom would sometimes take one or four months, and would then only serve for one particular pattern.

Early in the present century we were made with the view of rendering the draw-loom more automatic. On the ‘draw-loom’ there is no necessity of employing a boy to pull the handles, but removed, by the unerring certainty of its operation, all possible chance of mistake in pulling the wrong handle. This was a very ingenious arrangement of mechanism by which a treadle, worked by the foot of the weaver, gave a vibratory motion to a curved lever which drew down some of the warp threads and elevated others; and the skill consisted in so causing the lever to travel along a rack or toothed bar as to act upon different warp-threads in succession. The weaver, however, employed, while another invention, equally ingenious perhaps, has from various causes failed to come into use. This latter was the automatic carpet-loom of Mr. Duncan. Here the warp-threads, instead of being elevated and depressed by the handles as in a draw-loom, or by the reciprocating lever as in the draw-boy, were moved by pins inserted in a rotating barrel, the pins being placed in an order of succession according to the pattern to be produced, just as those on the barrel of a street-organ or a banjo. The several blocks are disposed according to the tune to be played.

But the draw-loom, the draw-boy, and the barrel-loom have been alike eclipsed by the exqui- }

site apparatus of M. Jacquard, which is very properly named after the inventor, M. Jacquard. This apparatus has been introduced into the Spitalfields, where the makers of mat and damask have long been the leaders; we therefore give a description of its principle and action. The Jacquard apparatus is intended to elevate or depress the warp-threads for the reception of the shuttle. There is a hollow prismatic box, whose surfaces are pierced with a great number of holes; and to each face of the box is fitted a card also perforated in such a manner that the number of holes is the same on each face of the box. The perforations in the cards, where they occur, are correspondent in position with some of the holes in the box; but in other places they are blank. The holes represented on these cards consist of two vertical holes, which may be one or two hundred in number, and all form an endless chain. The box may have four, five, or more faces, according to circumstances. The principle of action may perhaps be explained thus:—Supposing each face of the box to have one hundred perforations, then there are a hundred small bars or needles ranged in a group in exactly the same order as the holes in the faces of the box, the ends of the bars being immediately opposite the holes. Each bar or needle is a lever by which certain warp-threads are raised or depressed; the pins or the parts of the warp-threads are moved longitudinally, the warp-threads become elevated or depressed. Now if the box have a reciprocating motion, so that one of its faces shall strike against the ends of the bars, the ends of all the bars will pass into the holes, the warp-threads will be depressed; but if it be covered, some of the bars will pass through the holes of the card into the holes in the box, while others, at the unperforated parts of the card, will be driven aside. Thus the bars became unequally acted on, and they in their turn act unequally on the warp-thread, as the latter reciprocally, perhaps, from various causes failed to come into use. This latter was the automatic carpet-loom of Mr. Duncan. Here the warp-threads, instead of being elevated and depressed by the handles as in a draw-loom, or by the reciprocating lever as in the draw-boy, were moved by pins inserted in a rotating barrel, the pins being placed in an order of succession according to the pattern to be produced, just as those on the barrel of a street-organ or a banjo. The several blocks are disposed according to the tune to be played.

But the draw-loom, the draw-boy, and the barrel-loom have been alike eclipsed by the exquisitely apparatus of M. Jacquard, which is very properly named after the inventor, M. Jacquard. This apparatus has been introduced into the Spitalfields, where the makers of mat and damask have long been the leaders; we therefore give a description of its principle and action. The Jacquard apparatus is intended to elevate or depress the warp-threads for the reception of the shuttle. There is a hollow prismatic box, whose surfaces are pierced with a great number of holes; and to each face of the box is fitted a card also perforated in such a manner that the number of holes is the same on each face of the box. The perforations in the cards, where they occur, are correspondent in position with some of the holes in the box; but in other places they are blank. The holes represented on these cards consist of two vertical holes, which may be one or two hundred in number, and all form an endless chain. The box may have four, five, or more faces, according to circumstances. The principle of action may perhaps be explained thus:—Supposing each face of the box to have one hundred perforations, then there are a hundred small bars or needles ranged in a group in exactly the same order as the holes in the faces of the box, the ends of the bars being immediately opposite the holes. Each bar or needle is a lever by which certain warp-threads are raised or depressed; the pins or the parts of the warp-threads are moved longitudinally, the warp-threads become elevated or depressed. Now if the box have a reciprocating motion, so that one of its faces shall strike against the ends of the bars, the ends of all the bars will pass into the holes, the warp-threads will be depressed; but if it be covered, some of the bars will pass through the holes of the card into the holes in the box, while others, at the unperforated parts of the card, will be driven aside. Thus the bars became unequally acted on, and they in their turn act unequally on the warp-thread, as the latter reciprocally, perhaps
bestowed upon their performances the most painful amount of labour; the most beautiful products of the loom in the present day are however accomplished by men possessing only the ordinary rate of skill, while the labour attendant upon the actual weaving is but little more than that which makes the poorest goods.

Double Weaving.—In all the fabrics hitherto noticed, there is but one layer of threads, formed by the intersection of the web among the warp, both warp and weft being individually single. But there has long been practised the weaving of a kind of double cloth, composed of two webs, each consisting of separate warp and weft, but both sets interwoven at intervals. The junction of the two webs is formed by passing each of them occasionally through the other, so that each particular part of both is sometimes above and sometimes below. Kidderminster or Scotch carpeting is almost the only kind of double cloth now woven in this country; and it will therefore be sufficient for us to refer to the article Carpet for details.

Cross Weaving.—This term may be conveniently applied to those varieties of woven fabric in which the warp-threads, instead of lying constantly parallel, as in all the cases hitherto noticed, cross over or twist around one another, thus forming a plexus or interlacing independent of that produced by the weft. Gauze and Bobbin-net may be taken as the chief representatives of this kind of fabric. The former has been already slightly treated on [Gazze], and we will here glance rapidly over a few remarkable points in the history of the latter.

The production of light cross-woven goods, previous to the extraordinary development of the bobbin-net manufacture at Nottingham, was carried on only to a limited extent. Net was the generic name for these goods, and according as slight deviations were made in the mode of crossing the threads, so were distinctive names given to the material produced; such as whip-net, mail-net, patent-net, drop-net, spider-net, Paris-net, balloon-net, &c. All these varieties were produced at the loom, with warp-threads stretched horizontally, and weft-threads thrown across by means of a shuttle; and the difference between them depends on the manner in which the warp-threads were made to cross one another, and in which the web-thread was thrown. In the bobbin-net of later times however the plan is produced by a machine very different from the common loom, and among the most remarkable which our textile manufactures afford.

In 1777 a machine was invented at Nottingham for the manufacture of a kind of net on a principle somewhat similar to that of stocking-weaving; but this was soon superseded by another, which was manufactured what was then the point-net, invented by Mr. Lindley, and afterwards improved by Mr. Taylor and Mr. Flint. The point-net became so highly approved, that there were no fewer than 260 manufactories at work in the beginning of the present century. Next succeeded what was called the warp-net, which produced warp-net in successful competition with the point-net. Still however the net produced did not afford a good imitation of the bobbin-lace or pillow-net; and the Nottinghamshire net manufacturers threw out every inducement for the development of a machine which would produce such an imitation. At length, in 1809, Mr. John Heathcoat, a stocking-weaver of Loughborough, availing himself of an ingenious principle involved in a machine for making fishing-nets, invented a machine by Robert Brown, of Nottingham, produced and patented the bobbin-net machine, one of the triumphs of modern ingenuity. From this time a new field of industry became opened, into which capital and skill rapidly entered. The first of Mr. Brown's inch wide, the high bolt machine of Mr. Morley, the pusher-machine of Messrs. Mart and Clark, the circular-bolt machine of Mr. Morley, and the lever-machine of Mr. Leavers, were successive improvements on Heathcoat's bobbin-net machine, involving its main principle, but working it out more effectually.

The main points of difference between the bobbin-net machine and the common loom may be thus stated. In the former the warp-threads are vertical; in the latter they are horizontal; in the former they are doubled upon a brass bobbin so thin as to pass between the adjacent threads of the warp; in the latter it is contained in a shuttle an inch or more in width; in the former the transit of the web-thread, while passing between the warp, is at right angles to the plane of the web; the latter is parallel with that plane: in the former the successive meshes or intersections are driven up close to those before made, by a series of pointed wires catching in the loops; in the latter there are sometimes as many as three thousand bobbins or weft-carrying implements to one machine; in the latter there are seldom more than one or two shuttles: in the former each bobbin twists its web-thread round a warp-thread by a series of oscillatory movements of a pendulum; in the latter the twisting is effected rather by the movements of the warp than those of the web.

The activity to which the invention of the bobbin-net machine gave rise was quite extraordinary, and the profits accruing to the inventors were immensely great. In 1809 five guineas a yard was given for bobbin-net which can now be equalled for eighteen-pence; and quiltings or edgings, which obtained 4s. 6d. per yard in 1810, can now be equalled for three-halfpence. This enormous change which has been due partly to the introduction of the mechanical virtues of Mr. Brown's machine, and partly to the enormous progress of the manufacture, which are rendered all the more remarkable by the fact that in 1809 the manufactures of Nottingham and the adjoining villages, became the scene of an epidemic mania. Many, though nearly devoid of mechanical genius, or the constructive talent, tormented themselves night and day with projects of bobbins, pushers, looms, point-bats, and needles, dreams of wealth, and minds got permanently bewildered; several lost their senses altogether; and some, after cherishing visions of wealth, as in the old time of alchemy, finding their schemes abortive, sank into despair and committed suicide. 

] and certain statistical details which Mr. Felkin, of Nottingham, furnished to the Factory Commissioners about ten years ago, it appears that at that time the quantity of cotton used annually in 2,497,000 lbs., value about £100,000; that this was made into thirty million yards of net; value nearly two millions sterling; that 160,000 persons were employed in spinning, doubling, weaving, finishing, and embossing the net; that the fixed
and floating capital invested in the bobbin-net manufacture reached as high as two millions sterling; and that there were from four to five thousand bobbin-net machines then in England. Some of these machines produce net twenty-quarters or five yards in width; and it may with truth be said, that such a machine, with its three or four thousand delicately-arranged bobbins, and provided with a Jacquard apparatus, is one of the most exquisite pieces of mechanism which our manufactures can exhibit.

**Chain-Weaving.**—We may perhaps apply this term to a mode of using threads in which a series of loops is formed by means of a number of bobbins, the threads being interwoven with others as to form a kind of chain; and this chain-work may either be worked upon a ground woven at the loom, or may constitute the woven material itself. In the common kind of bobbin-net, that is, in which the warp is covered with silk or covered with threads, the warp of silk is covered with figures or letters by coloured threads, worked with the needle, the woven piece being held in the left hand. In the ‘lace-running’ and ‘tambouring,’ largely carried on in and near Nottingham, the operation approaches more nearly to a kind of weaving; for the bobbin-net, which forms the ground, is stretched horizontally on a frame (see ‘Penny Magazine,’ No. 700), and the lace-runner works a series of ornaments in the net by a needle threaded with coarse cotton, the pattern being previously marked or traced on the net. In the ‘hoop-net,’ a new kind of bobbin-net, the cotton thread is carried and fro between the meshes of the net by means of a very fine and small hook, which gives to the decorative figure thus produced much more the appearance of chain-work than the instance above mentioned. This kind of weaving was introduced into England in the early part of the present century to have occupied the early part of the present century to have occupied twenty thousand females in Great Britain, the muslin is stretched over a hoop, and there kept in its place by an ornament, which is thence, the hoop is then either between the knee and the chin of the operator, or (more generally) by a kind of pedestal, while the work-woman produces a kind of chain-work on the surface of the muslin. About thirty years ago Mr. Duncan invented a very ingenuity of the kind, which he described in his ‘Brewster’s Edinburgh Encyclopædia;’ but it does not appear to have maintained a permanent footing. More recently a method has been introduced at Manchester of embroidering silk goods by means of an ingenious instrument whose movements are governed on the principle of the pantograph. [PANTOGRAPH.]

Another kind of weaving which, coming midway between common weaving and needle-work, and combining something of the two, and ranked in the present class, is that which relates to rug-work and tapistry, in which, by means of links, loops, or stitches, various coloured threads are interwoven into a plexus or web, having an ornamental de

**The Manufacture of Stockings.**—The manufacture of stockings, whether by the humble process of knitting or by the use of the stocking-frame, is in strictness to be called ‘chain-weaving:’ for the fabric itself is actually produced by a series of links or loops in a thread of worsted, cotton, or silk. In the process of knitting, instead of one or a small number of districts, polished steel needles or wires are used to link threads together into a series of loops, closely resembling in their character the loops produced in tambouring. But the method has been almost entirely superseded by the ingenious **stocking-frame**, which we proceed to next notice.

A singular confusion pervades the early history of the stocking-machine, which neither Beckmann nor any other important inventor is connected in modern literature. There is a great jumble of persons, places, and dates in the accounts given of the invention and the inventor; but the version most generally received, and which is deemed to be corroborated by a picture and an inscription in the Stocking-weavers’ Hall, runs nearly thus: William Lee, of St. John’s College, Cambridge, was about the year 1589 expelled from the university for marrying contrary to the statutes. Having no fortune, the wife was obliged to contribute to their joint support by knitting; and Lee, while watching the motion of his wife’s fingers, conceived the idea of imitating those movements by a machine. According to another version, Lee, while yet unmarried, excited the contempt of his mistress by contriving a machine to imitate the primitive process of knitting, and was rejected by her; but both accounts agree that the stocking-frame was invented by Lee, and at about the date assigned. Having caught the use of the machine from his mistress and the rest of his relations, he established himself at Culverton, near Nottingham, as a stocking-weaver. After remaining there five years, he applied to Queen Elizabeth for countenance and support; but finding himself neglected both by her and by her successor, he came over to France, where Henry IV. and his sagacious minister Sully gave the inventor a welcome reception. On the death of the king, Lee shared in the persecution suffered by the Protestants, and was carried into prison. Sully, with grief and disappointed, at Paris. Some of his workmen made their escape to England, and under Aston, who had been Lee’s apprentice, established the stocking manufacture permanently in England.

In the year 1691, granted to the Frame-work Knitters’ (stocking-makers) Society of London a charter, which had been refused to them a few years before by Oliver Cromwell. Six years afterwards the number of stocking-frames in England amounted to 700, employing 1200 workmen, and the production of stockings amounted to millions; and the others: worsted for cotton was not then ranked among English manufactures. By the year 1714 the number of frames had increased to 8000 or 9000. Some years after this, the Frame-work Knitters’ Company attempted to restrict the woven stockings to cotton, on the ground that they were made up by the female hand, and that there was no advantage in the making and selling of the stockings; but the project failed. By the year 1733, about twenty years after the introduction of cotton stockings, the number of frames in England was 14,000. Mr. Jedediah Strutt of Belper, invented a frame which was a great improvement, and the stockingframers: he patented the machine, and the patent was twice contested, first by the hosts of Derby, and then by those of Nottingham; but the validity of the patent being established a few years later, he brought to market the machine which led by gradual improvements to the net-machines.

The common stocking-frame exhibits a quadrangular arrangement of upright posts, connected by cross-pieces at the top, and having on one side an additional piece of framing to support the weaver’s seat. Near where the weaver sits is placed a series of needles, which serve the placing of knitting-neddles in forming the loops; they are not straight needles, nor yet what would be termed hooks, but somewhat resembling a curling piece, or very short lancets, and they all act through the meshes of the frame and the whole of the needles depend upon the coarseness or fineness of the stocking. This degree of fineness is represented, for no adequate reason that we are aware of, by the number of loops contained in three inches of breadth, which varies from about forty to upwards of one hundred, or even more, for coarse or, as applied to hosiery. The stocking-frame is provided with a series of vibrating levers, called jacks, and these jacks, aided by other intricate apparatus, throw the stocking-yarn into such curvatures as to enable the needles to form the loops. The weaver has a bobbin of yarn on one side of his frame, from which he unwinds enough to lay across all the wires; he then, by moving certain treads with his feet and levers with his hands, forms this length of yarn into a round loop, and at the next movement, when forming another row of loops, he引 their number one row into the other, so as to form a kind of chain, which chain, extending both lengthwise and across, constitutes the web of the stocking. The precise mode of producing, even the length and breadth, and illustrated by figures, is exceedingly difficult to comprehend; and we shall therefore not enter into details unsuitable to our limits. Suffice it to say that one continuous thread forms both warp and weft, if we may apply these terms to the stocking-frame, as well as the common weaver, who is tied to knots such as occur in making nets, the meshes are loose, and may be easily undone if not secured at the edges, but at the same time the web acquires a degree of elasticity which no other form of woven plexus presents. A few statistical details, and a notice of a machine for making twelve stockings at once, will be found under Hosiery; while the following, from the evidence collected by the Factory Commissioners, will show the mode of conducting the stocking-trade. There are three classes of
operatives engaged: the 'winders,' who put the silk, cotton, or thread on the bobbins: the 'stockingers,' or 'frame-work' 'knitters,' who work the thread up into a knitted fabric; and the 'seamers,' who make the stockings out of the pieces of the goods. A great number of small children, who can wind thread enough for half a dozen machines each; the 'knitters' are men, women, and youths, who hire both the winders and the seamers; and the 'seamers' are women. Some of the stocking-frames are open, in which the women are worked at home, and some are closed, in which the women are worked out to the men by the owners at so much per week for each frame; while other persons are renters of what is termed a 'shop of frames,' containing eight or ten frames, let, with standing-room, &c., to the workmen. The house-keepers are generally of the latter class, paying a certain sum, usually a guinea per week, giving a workman a week to the holders of a shop of frames; and these latter charge that same sum, or perhaps three pence more, to the journeymen or real workers, with the addition of 'a piece of the shop-rent.' It is thus that such difficulties arise for the trade of knitting, and may be due to the great extent of it, and the fact that the trade is not in the hands of manufacturers.

Some of the stocking-frames are an inch or more, and the women are worked at home, and some are closed, in which the women are worked out to the men by the owners at so much per week for each frame; while other persons are renters of what is termed a 'shop of frames,' containing eight or ten frames, let, with standing-room, &c., to the workmen. The house-keepers are generally of the latter class, paying a certain sum, usually a guinea per week, giving a workman a week to the holders of a shop of frames; and these latter charge that same sum, or perhaps three pence more, to the journeymen or real workers, with the addition of 'a piece of the shop-rent.' It is thus that such difficulties arise for the trade of knitting, and may be due to the great extent of it, and the fact that the trade is not in the hands of manufacturers.

Pile Weaving.—If we examine a piece of silk velvet, or any kind of fustian, such as velvetee, moleskin, or doe-skin, or a Turkey or Wilton carpet, we shall find that in any or all of these fabrics the warp and weft threads are apt to be cut for further use, and the resulting surface surface in the nature of a pile, or a moulding, which adds greatly to the beauty of the fabric. In some kinds of fustians the pile is cut so as to impart a peculiarly soft and smooth texture to them. It may seem strange to class together such very different materials as silk velvet, fustian, and Turkey carpeting; but the classification is strictly correct, because all of them are examples of the same operation, and are made on the same power-loom, which is adapted to the nature of the design. But there is, besides the warp and weft properly so called, another kind of warp, whose threads are laid standing in loops above the general surface, and are cut, and the cutting of which constitutes the pile. In some kinds of fustians the pile is cut so as to give a smooth velvet surface; while in other kinds it is cut into parallel cords, forming corduroy and such like fabrics. The cutting used formerly to be done by peculiarly shaped knives held in the hand, but some very ingenious machines have been contrived for effecting it more quickly and correctly. For the application of this peculiar manufacture to different fabrics, see Carpet; Fustian; Velvet.

Power-Weaving.—In all the kinds of weaving hitherto noticed it has been a matter of very great advantage to use double cloth, bobbin-net, stockings, or velvet fabrics, we have uniformly spoken of the weaving-machine as being worked by hand, or rather by hand and foot, for a tredle is an almost invariable component part of such a machine. We may speak of the tredle as a component part of the machine, and the steam-engine as the essential element, by which the steam-engine has been brought to bear on this department of industry.

In the 'Philosophical Transactions' for 1768, a loom, invented by M. de Gennes, is described as 'a new engine to make linen cloth with the aid of an artificer, by applying water-power as the moving force.' The advantages are 'thus enumerated: 1. That one mill alone will set ten or twelve of these looms at work; 2. The cloth may be made wider in one day than any which has been hitherto made; 3. There will be fewer knots in the cloth, since the threads will not break so fast as in other looms, because the shuttle that breaks the greater part can never touch them. In short, the work will be executed faster and in their finished state, and the expense of the power of the present day; but we have no evidence that De Gennes's machine ever came into use. At various times during the last century, M. Dolignon, M. Vaucanson, Mr. Austin, and Mr. Millet contrived looms which were to be worked by water, and besides some considerable expediency, the ordinary hand-loom. A model of Mr. Austin's machine is deposited in the museum of the Society of Arts; and Mr. Porter, in his 'Treatise on the Silk Manufacture,' has given a representation and description of its mode of action. The first power-loom for weaving was very simply carried out by Mr. Austin in the factory of Mr. Monteuil, near Glasgow, in 1798; but before that time another machine had been invented, whose history is curious and interesting.

The Rev. Dr. Cartwright, brother of the late Major Cartwright, happening in 1768 to be in conversation with some gentlemen concerning Arkwright's spinning machinery. It was observed that, so soon as Arkwright's patent expired, so many mills would be erected, and so much cotton spun, that hands would not be found to weave it, and a necessity might arise for inventing a new mode of spinning. And this case, invent weaving machinery; and the idea, thus suggested by himself, seems to have taken hold of his mind; for he soon afterwards endeavoured to form a machine which should imitate the three movements of the weaving machine. He succeeded so far as to produce a machine, which he patented in 1785; and another, for which a patent was obtained in 1787. He tried to establish a power-loom weaving factory at Doncaster, but failed; Messe, Grimshaw and others employed some 100 of Mr. Cartwright's machines at work at Manchester, but similarly failed from various causes; and, after many years of labour, many patents, and an expenditure of 40,000l., Dr. Cartwright was compelled, in 1808, to ask for a grant from Parliament as a means of overcoming the difficulties of the cotton trade. Parliament awarded him 10,000l.

One cause which delayed the adoption of power-looms was the necessity for stopping the machine frequently, in order to dress the warp as it unraveled from the beam, which was the principal operation required in the hand-loom, so that there was no saving of expense. In the year 1822, Mr. Radcliffe, a cotton manufacturer of Stockport, aided by a workman, Thomas Johnson, made many contrivances with a view to remedy this inconvenience, and the inventor to whom the honour of being the first to introduce modern factories, by which the warp is dressed before it goes into the loom. At a subsequent period Mr. Horrocks and Mr. Mainland, both of Stockport, made other improvements, which brought the power-loom entirely into use for weaving operations, and thus power-looms became established. Still more recently, Mr. Roberts, of the firm of Sharp and Roberts, at Manchester, has brought the power-loom to a state of high perfection; and every year sees the number of such looms employed in manufacturing districts.

The application of the power-loom renders necessary the employment of other machines likewise, to effect those preparatory operations which, in hand-loom weaving, are carried out by the hands of the weaver. Mr. Austin called calico as the representative of plain fabrics generally, the mode of proceeding in power-loom factories may be shortly sketched as follows:—

The warping-frame instead of being employed on the same principle as the warping-mill sketched in a former page, is so arranged as to be worked by steam-power. Several bobbins, arranged with their axes parallel and horizontal, in a compartment at one end of the frame, yield the yarn which is to be collected into a warp. The bobbins, proceeding from the bobbins, pass under some rollers and over others, until all are brought into a parallel layer, a comb of fine wires being employed to separate the yarns equally. The yarns are then collected and coiled as in any other frame, and are put into the warp-frame, and transferred to the dressing-machine. This latter is a large piece of mechanism, by which the contents of eight rollers from the warping-frame are collected on one roller or beam, which is to form the warp-beam of the web. The yarns, passing through the paste or mucilage-drying, and dried. Four of the rollers are placed at one end of the machine, and four at the other; and the yarns, proceeding from thence, pass between rollers, of which the lower one is polished, and becomes thus coated with it; they are then passed under and over brushes, by which the paste is rubbed into the fibres; then over a steam-heated copper box, by which they are dried, and, lastly, are wound on the warf-beam.
two or three hundred bobbins, arranged through a comb or reed, coated with paste, rubbed with the brushes, dried over the steam-heated boxes, and wound on the warp-beam; thus combining both warping-frame and dressing-machine in one.

The preparation of the warp in the loom, comprising what are called the ‘drawing’ and ‘mounting,’ is more simple for the power-loom than for the hand-loom, but is still somewhat intricate. When however this is effected, steam-power does all the rest: it forms the shed or division of the warp into two parts; it throws the shuttle; it drives up the west with the batten; it unwinds the warp from the warp-roller; and winds the woven material on the cloth-roller. Part of these operations may be illustrated by Fig. 6, in which some of the mechanism is omitted to render the rest more clear. The warp, un

wind from the beam A, and bordering round the roller B, passes through the two leaves of healds CC, by which the shed is formed for receiving the shuttle at D; and after the weft of the batten (not here shown) the finished cloth E results.

The pressing, finishing, dressing, &c., which the woven goods receive, whether woven by the power-loom or the hand-loom, depend, of course, on the nature of the fabric. One of the most important of these, by which the plain goods become diversified with ornament, is detailed under CALICO PRINTING.

With a few remarks on the recent progress of power-weaving, we shall conclude. Mr. Baines, about eight or nine years ago, arrived at an opinion, from the estimates of Messrs. Cleland, Kennedy, Greg, Banffy, and others, that there were, at that time, 83,000 power-looms in England, and 15,000 in Scotland; and he stated that while power-looms were rapidly increasing every year, there was no proof that hand-looms had diminished. The number of the latter, at various times between 1824 and 1833, has been estimated at from two to three hundred thousand. Up to the year 1833, the weaving by power-looms was chiefly confined to calico and furnishing; but it is gradually being employed for other fabrics. There is one cotton factory at Stockport in which 1300 power-looms are employed in weaving calico; and many other factories exhibit an equal, or nearly equal, amount of operations.

What must be the ultimate effect of this system upon the fortunes of the hand-loom weavers? it is difficult to say. A boy or a girl, managing two power-looms, can produce three or four times as much cloth in a given time as the best hand-weaver; and cloth, too, which is much more uniform in its texture. The wages per piece become thus driven down step by step, and the hardly-earned pittance of the hand-loom weaver is scarcely sufficient for his support. The Parliamentary documents, published within the last ten years, comprise several large folio volumes relating wholly to inquiries made into the condition and prospects of the hand-loom weavers. In Mr. Hickson’s notes and observations on this subject, forming one of the Parliamentary reports for 1840, he gives a comparative view of the present state of the four principal classes of hand-loom weavers, and then considers the various arguments which have been brought forward in support of certain remedies for the present depression. The conclusion at which he arrives is similar to that of Mr. Baines, who, shortly before, had hailed with satisfaction the fact that many hand-loom weavers had gone to work in the steam factories: deeming it the only remedy for their present state. Mr. Hickson’s words are:—The trade of hand-loom weaving is not only incapable of improvement, but of remaining in its present state. In the years 1790, 1791, 1792, 1793, the weaver were those who would advise and assist him to transfer his labours to other channels of industry. But owing to the hand-loom, his condition will become worse from day to day. A few of the more skilled classes of weavers may indeed maintain their position, but the fate of the many (unless their intelligence and foresight avert it by change of occupation) is decreasing employment, decreasing wages, and ultimate destitution. (Reports from Commissioners, 1840, vol. i., p. 659.)

WEBB, S. W. [WEAVING.] WEBBE, SAMUEL, an eminent composer of that part-music which we may justly claim as national, was born in the year 1740. His father was a weaver, and held an office under the British government at Minorca, dying suddenly, and leaving his property in such a state that his family never profited by it; his widow was unable to give her son a liberal education, and at the age of eleven he was apprenticed to a cabinet-maker. On the completion of his term, however, he abandoned a pursuit so little suited to his expansive mind, and commenced the study of the Latin language. But his mother dying shortly after, he was reduced to the necessity of following the example of J. J. Rousseau, and copied music as a means of subsistence, though knowing but very little of the art. This led to an acquaintance with a German, named Barbandt, organist of the Bavarian chapel, who initiated him in the principles of music. His unwearying industry and patience enabled him not only to support himself by copying, but to acquire, in addition to the Latin, a knowledge of the French and Italian languages. He now began to give lessons in music, and soon after to compose, and was so successful in the latter attempt, that, at the age of twenty-six, he gained a gold prize-medal from the Cuck-Church for the best canon. In 1768 he was rewarded, by the same elegant society, by a medal for his simple but beautiful glee, ‘A generous friendship no cold medium knows,’ which immediately established his reputation.

From the year which first witnessed his success as a composer, to 1792, Mr. Webb had twenty-seven medals awarded to him by the same club, for glee, catches, canons, and odes. But it is worthy of remark, that four of his finest works, including that matchless production, ‘When winds breathe soft,’ failed in obtaining the golden honours bestowed on works of far inferior merit. And it must be confessed that some of his medals were given him for compositions now forgotten; among which too many were the reward of useless pieces of musical mechanism, called canons.
In 1814 Mr. Weber was appointed to succeed Mr. War- 
ren Horne, as secretary to the Catch-Club; and in 1879, 
on the establishment of the Gluck Club, he became a pro-
fessional member and the librarian. It was for this society 
he wrote both words and music of his popular gleé, 'Glo-
rious Apollo.' But amidst his professional avocations he 
fixed his first productions, consisting of six fugheetti, which was very favourably noticed in the German 'Musical Gazette' of that year. Shortly after this he went to Munich, where he received lessons in 
angage from the organist of the Bayerische Hofkapelle, 
and in composition from the organist of the Augustiner 
capitel, which however he candidly tells us were 'wisely 
committed to the flames.'

About the same time the art of lithography was first 
discovered, and the restless activity of the youthful 
man, which embraces with eagerness all that is novel, 
driven the young composer's attention from his legitimate 
study, and involved in him the ingenious inventor of that art. He procured 
the necessary tools, and setting himself vigorously at work, 
at length almost fancied himself the original inventor: at 
least, he says, he felt sure that he included the impreg-
nated system, and could construct more perfect machinery.

Impressed with this belief, he urged his father to remove 
to Freyburg, where all the necessary materials could be 
more readily procured. The man however quickly perceived 
the usefulness of his parents' knowledge, and annexed 
the establishment of this art, and immediately 
increased zest to his musical pursuits.

Weber now set to work on Schumann's opera, 'Das Wald-
mädchen' ('The Wood-girl'), which was performed in 1800, 
and spread further than, at his mature age, he thought 
desirable. It was, he says, a very crude jeneu work, 
though in some parts not altogether destitute of invention. 
The work was composed with a youthful affectation of promptness which he honestly 
acknowledged, and deplores. Being called to 
Salzburg, he there, in 1801, composed 'Peter Schollin.' 
in 1802 his father proceeded with him on a musical tour to 
Prag, Hamburgh, and Leipzick, and there 
work was the only thing that he could 
endeavour to do. After this, he found 
Fulhild, his second son, and 
three years after, in 1805, at 
Hildburg, he was accorded for his skill as a 
player and composer. He and his 
father lived alternately in oil, in water-colours, and in crayons. 
He likewise acquired some degree of skill in the use of 
the etching-needle, but he did not follow up these 
employments with ardour, and they were silently suffered to be 
discontinued. In the years 1807 and 1809, he 
was conscious of its influence, and at last entirely 
planted his sister as a 
father of music. His father frequently changed his 
place of residence, and this led as frequent change 
in his sons' masters, who too often undid what had been 
done. The duties of the pupil were not always more 
than compensated, by compelling him to become his own 
officer, and to depend on his own energies. He 
worked, compared, and reflected, and sought to reduce 
well-grounded principles, especially in music, from what 
he had heard, read, and thought. To Hauschel, of 
Hildburg, he was indebted for his skill as a 
flute-player; and he mentions in warm terms of gratitude the 
advantages he derived from this master during the years 
1807 and 1809.

In 1810 Weber now observing the great and decided develop-
ment of his son's musical talents, took him to Salzburg, 
and placed him under the tuition of Michael Haydn, 
brother of the illustrious composer, and himself a very 
learned musician; but though the pupil laboured with 
rareness and industry, his progress was slow and 
meagre. The master was then at an advanced period 
of life; he was grave, not to say severe, in his manner. There 
was in the tone of the distance between old age and 
childhood. At Salzburg, in 1798, his father, as an 
detachment, printed his first production, consisting of 
6 fugheetti, which was very favourably noticed in the German 'Musical Gazette' of that year. Shortly after 
this he went to Munich, where he received lessons in 
angage from the organist of the Bayerische Hofkapelle, 
and in composition from the organist of the Augustiner 
capitel, which however he candidly tells us were 'wisely 
committed to the flames.'

In 1802 his father proceeded with him on a musical tour to Belin, 
Hamburgh, and Leipzick, and there 
work was the only thing that he could 
endeavour to do. After this, he found 
Fulhild, his second son, and 
three years after, in 1805, at 
Hildburg, he was accorded for his skill as a 
player and composer. He and his 
father lived alternately in oil, in water-colours, and in crayons. 
He likewise acquired some degree of skill in the use of 
the etching-needle, but he did not follow up these 
employments with ardour, and they were silently suffered to be 
discontinued. In the years 1807 and 1809, he 
was conscious of its influence, and at last entirely 
planted his sister as a 
father of music. His father frequently changed his 
place of residence, and this led as frequent change 
in his sons' masters, who too often undid what had been 
done. The duties of the pupil were not always more 
than compensated, by compelling him to become his own 
officer, and to depend on his own energies. He 
worked, compared, and reflected, and sought to reduce 
well-grounded principles, especially in music, from what 
he had heard, read, and thought. To Hauschel, of 
Hildburg, he was indebted for his skill as a 
flute-player; and he mentions in warm terms of gratitude the 
advantages he derived from this master during the years 
1807 and 1809.

In 1810 Weber now observing the great and decided develop-
ment of his son's musical talents, took him to Salzburg, 
and placed him under the tuition of Michael Haydn, 
brother of the illustrious composer, and himself a very 
learned musician; but though the pupil laboured with 
rareness and industry, his progress was slow and 
meagre. The master was then at an advanced period 
of life; he was grave, not to say severe, in his manner. There 
was in the tone of the distance between old age and 
childhood. At Salzburg, in 1798, his father, as an 
detachment, printed his first production, consisting of 
6 fugheetti, which was very favourably noticed in the German 'Musical Gazette' of that year. Shortly after 
this he went to Munich, where he received lessons in 
angage from the organist of the Bayerische Hofkapelle, 
and in composition from the organist of the Augustiner 
capitel, which however he candidly tells us were 'wisely 
committed to the flames.'

In 1810 Weber now observing the great and decided development of his son's musical talents, took him to Salzburg, and placed him under the tuition of Michael Haydn, brother of the illustrious composer, and himself a very learned musician; but though the pupil laboured with rareness and industry, his progress was slow and meagre. The master was then at an advanced period of life; he was grave, not to say severe, in his manner. There was in fact too awful a distance between old age and childhood. At Salzburg, in 1798, his father, as an detachment, printed his first production, consisting of six fugheetti, which was very favourably noticed in the German 'Musical Gazette' of that year. Shortly after this he went to Munich, where he received lessons in angage from the organist of the Bayerische Hofkapelle, and in composition from the organist of the Augustiner capitel, which however he candidly tells us were 'wisely committed to the flames.'

the first two years, nearly the whole of his attention. But his account of himself and his compositions seems to have been discontinued in 1818, and we have no means of filling up the interval between that period and 1822, in which year the first sort of, at Berlin, his present work, 'Der Freischütz,' the text, or libretto, by his friend and countryman Kind. Not only the novelty and beauty of the music, but the deep thought it evinced, immediately excited an extraordinary sensation in the north of Germany; and a copy of the manuscript has been sent to the editor of the 'Harmonicon,' an extract from it appeared, in January, 1823, in the first number of that periodical. This gentleman lost no time in mentioning the opera in strong terms to the proprietor of the English Opera-House. Judging from the expense of bringing it up, the decline of the dramatic contemporaries, has left few authentic records of his career, beyond his works. We know not where he was born nor where he was educated. The earliest notice we find of him is in the papers of Henslove, where he mentions as writing plays in conjunction with Dr. Webster, Drayton, Middleton, Stephen, and others. His works were performed by the Opera-House, and afterwards to Covent Garden, but with a similar result. However, other specimens of the work, and among them the beautiful Cavatina appearing in the 'Harmonicon,' and public attention having thus been called to it, the opera was at length performed, July 23rd, 1824, at the English Opera-House, and produced as great an effect in London as it had done in Berlin. In the following October it was given at Covent Garden theatre, and in November at Drury Lane, with the most brilliant success at both houses. On the 8th of December 'Der Freischütz,' under the title of 'Robin des Bois,' was brought out in Paris, at the Odéon, and for two weeks a most marvellous improvement on a French as on an English audience, its effect was sufficiently flattering to the composer, who nevertheless had great reason to complain of the iniquitous means by which his music had been procured, and of the imperfect manner in which it had been performed. Two of his two propositional letters to the manager of the Odéon on this subject were published in the 'Harmonicon,' vol. iv., p. 41.

In November, 1823, Weber produced at Vienna his 'Euryanthe,' which was not at first received with the enthusiasm which had followed his 'Oberon' and 'Der Freischütz.' It had, a serious, and certainly not written in a popular manner; but the more it became known, the more it was admired, and the overture is one of the composer's happiest flights of genius.

In 1825 Weber received a visit at Dresden from Mr. C. Keble, then the impresario of Covent Garden theatre, for the purpose of inviting him to compose an opera for the English stage, and to superintend its production in London, an engagement which he willingly undertook. The term of the contract was a hundred and twenty-seven representations, twenty-four of which were conducted by the composer. But it was now apparent that he was suffering under pulmonary disease. His journey to London in an unsavoury season, and his arrival in February, in the midst of the worst weather possible, aggravated his malady; nevertheless he bore up manfully against his sufferings. On the 26th of May he had a benefit concert at the Argyll Rooms; but we regret to add, says the 'Harmonicon,' and blushed for our country when we stated it to him, that the house was absolutely empty, and those who were unaccustomed to music of so original and high an order, yet they were fully felt by competent judges. The author was greater in the most cordial manner by the audience, and thoroughly satisfied with his public reception. Of the composition, which had been written in six months, and produced in three hundred academic dissertations. All his works display great research as well as learning. He was not only a good classical scholar, having had it in contemplation at one time to publish an edition of the Greek Bible, but he was also well versed in Oriental and Arabic. In his medical opinions he was a disciple of Van Helmont and Sylvius, and he adopted without enquiry the absurd opinions of these writers on the action of medicines. Amid the immense mass of his writings there is much that is valuable. His knowledge of the language and literature of the Orient was increased by the occupation of the opinions of others to have any of his own, so that his influence has been much less than many of whose writings do not amount to a tithe of that of his master. He had a large private practice, and was remarkable for the judiciousness of his manner in conversing on public matters, so much so that all his biographers express surprise at the great amount of his labours. He was held in much esteem by the men of his day. He was a member of the Leopoldine Academy, under the name of Hercules, and also a Fellow of the Royal Society of Edinburgh and
WED

many other learned societies. He was first physician to the Duke of Saxe Weimar, and also to the Elector of Mayence; and in 1604 he was created a count-palatine, and made an imperial counsellor. He was married for the third time in his sixty-third year, and had several children by this marriage. He died suddenly from disease of the heart, in the seventy-seventh year of his age. Although a voluminous writer, he was not in advance of his age in scientific acquirements. It is not therefore a matter of surprise that he was a believer in astrology, an art which he pursued with much zeal. It is too often the case in the medical profession that those who linger over the records of past experience fail to cultivate their powers of observation and reflection, and thus become the dupes of systems that have scarcely in fact a shadow or show of truth.

Wedel had several sons, who were distinguished men in the medical profession. Extent Wedel was born in 1671, and died in 1709. He followed in the footsteps of his father. He published a work on the diseases of orators, 'De Morbis Conjunctionorum,' which went through two editions. JOHANN ADOLF WEDEL was the eldest son of his father, and was born in 1695. He has also written a large number of works, the chief of them academical dissertations.

The following are some of Wedel's numerous works:—

'Dynagra,' 1674, Jenae, 4to.; 'Exercitationes Pathologicae,' 1685, Jenae, 4to.; 'De Medicamentis Facultatibus, cognoscendis et applicandis Libri Duo,' 1678, Jenae, 4to.

This work has been translated into English. 'De Medicamentorum Compositione extemporanea ad usum hodie accommodata,' 1709, Jenae.

This work is still spoken well of, and Wedel has still the reputation of having been an accomplished prescriber.

(Biographie Medicale; Jocher, Allgen. Gelehr.-Lett. Eloy, Dict. Historique de la Medecine.)

WEDEL, in Mechanics, is a prism of wood or metal whose base is a triangle: it is employed to remove two objects from one another laterally, or to rend asunder the parts of a body; an edge which is parallel to the geometric base of the prism being introduced between the body or parts of the body, and the whole wedge being then driven forward by a percussive force, as the stroke of a hammer. The nature of percussive force, and of the resistance which a yielding material opposes to the motion of the wedge, however, imperfectly known, it is usual to consider the motive-power and the resistance as simple pressures, or weights, in estimating the conditions of equilibrium when a wedge is employed as a machine.

Let ABC represent the section of a wedge perpendicularly to the mathematical axis; and for simplicity, suppose this section to be an isosceles triangle. The plane passing through AB, perpendicular to ABC and to the paper, is called the head or back of the wedge: the plane passing through AC and BC perpendicular to the paper are called the sides; and their line of section, passing through a, and b, is the edge. The motive-power is applied to the head of the wedge; and may be supposed to act in the direction MC perpendicularly to that plane, and passing through C in the edge. Let the material which is to be rend asunder be in contact with the sides of the wedge in lines passing through a and b perpendicularly to the paper; and let the two parts yield as if they were capable of turning about some point c in the direction of MC, produced if necessary: then it is evident that the effect of the wedge will be the same as if a section made perpendicular to the axis, were abc. Imagine ad, bd to be drawn perpendicularly to ac and bc; then those lines will meet at a certain point, as d, in the line MC: imagine also the parallelogram adBD of forces to be constructed; then dD for 2aD will represent the motive force, and da or db the pressure which that force exerts at a or b perpendicularly to ac and bc. Let P represent the motive force, and R the pressure at a or b; then, in a state of equilibrium, the latter will represent the reaction of the material in the direction ad or bd. But we have

\[ P : R = 2aD : da. \]

But the triangle aNd is similar to cNa; therefore

\[ dN : da : aN : ac, \]

and consequently

\[ P : R = 2aD (\equiv ab) : ac. \]

The point of the position c where the separation of the material is supposed to take place varies for different materials, and can only be estimated, or found from experiment: if it were supposed to coincide with C, we should have

\[ P : R = 2aN : aC; \]

or by similar triangles aC, ABC.

\[ P + R = AB : AC. \]

If the force of the wedge at the points a or b were to be estimated in the direction Na or N\bar{a}; as when it is required, neglecting friction, to find the force with which a given pressure P in the direction MC, on the head of the wedge, would make a body at a or b slide in a direction coinciding with C, then, R being the force, and C coinciding with C, or ad being now perpendicular to AC, we should have

\[ P : R = 2aN : Na, \]

or as 2aN to NC, or as AB to EC.

The point c still coinciding with C, let \( \theta \) represent the angle AEC, half the angle of the wedge: then

\[ aN = \sin \theta, \quad \frac{AB}{AC} = \sin \theta; \]

also AB : EC = 2 sin \theta = \cos \theta;

it follows, radius being unity, that

\[ P : R = 2 \sin \theta : 1, \quad \text{or} \quad P = 2R \sin \theta; \]

also \( P + R = \sin \theta : \cos \theta, \) or \( P = 2R \tan \theta; \)

where R and R' represent the pressures perpendicular to AC and to EC, respectively.

If it were required to find an equation for the motion of a wedge when acted upon by a force of percussion, a process corresponding to that which follows must be employed.

Let, as before, ABC be a section of the wedge, which may be supposed of iron; let it be introduced between the parts of a body which can yield only in a lateral direction: and let it be driven by a mass of iron falling upon it from a point at some given height above it. Both the wedge and the hammer, or falling body, must be understood to be elastic; and it will be convenient to represent the latter by a parallelopiped of iron whose base is equal to the rectangular head of the wedge: let the height of such solid be represented by P, and let the space through which it is supposed to fall be represented by b; then, by Dynamics, \( 2gb \) will be equal to the square of the velocity of impact. In like manner let the friction of the wedge, estimated in a direction parallel to CM, be represented by the weight of a parallelopiped of iron whose base is the rectangular head of the wedge, and let the height of such parallelopiped be represented by \( \frac{P}{Q} \).

When the collision takes place, both the falling body and the wedge will be compressed in the direction of their length. Let the linear contraction of P be represented by \( \alpha \), and that of the wedge supposed at present immovable, by \( \varphi \) (both \( \alpha \) and \( \varphi \) coinciding in direction with MC). Then \( \varphi \) represent the modulus of elasticity (or the height of a vertical column of iron, having a base equal to the head of the wedge, whose weight would, if it causes, reduce the height P or Q of the supposed masses of iron to zero) and the forces of compression be assumed proportional to the contractions which they produce, we shall have \( \frac{P}{Q} = \frac{\alpha}{\varphi} \) for the forces by which the falling body and the wedge are respectively compressed in consequence of the collision; or the forces by which
which they tend to recover their original state: let these be represented by \( mp \) and \( m q \) respectively; or, in terms of the force of gravity, by \( m g p \) and \( m g q \). Then \( n g q \) will represent the motive force by which the movement of the falling body is resisted after the impact, or \(-\frac{n g q}{P} \) will represent the retardative force against that body.

But from the equality of action and reaction we have

\[ mp = nq \]

whence \( p = \frac{nq}{m} \), and \( p + q \) or the sum of the compressions, is equal to \( \frac{n + m}{m} q \); let this be represented by \( s \); then \( q = \frac{ms}{n-m} m \) and \( P = \frac{mn_p}{n+m} m \). Now, by Dynamics, accelerative or retardative force is represented by

\[ \frac{dv}{ds} \]

and the velocity of the falling body at any time \( t \) between the instant of impact and that at which its motion is extinguished by the resistance: therefore

\[ \frac{dv}{ds} = -\frac{m n g s}{(n+m) P} \]

and integrating, \( V \) representing the velocity at the instant of impact, at which time \( s=0 \),

\[ V = V_0 - \frac{m n g s}{n+m} \]

But when the wedge begins to move, the friction is equal to the force by which the falling body is compressed; therefore, making \( Q \) equal to \( m n s \) or \( (nq) \) we have

\[ s = \frac{(n+m) Q}{mn} \]

which being substituted in the above equation, we have

\[ V = V_0 - \frac{(n+m) Q}{mn} \]

Now the wedge being uniformly resisted by friction while moving in consequence of the impact, the retardative force \( f \), expressed in times of gravity, will be \( \frac{Q}{P} \).

\[ W \]

representing the weight of the wedge in terms homologous to \( P \). Therefore since, by Dynamics, \( s = \frac{tv}{Q} \); if we represent the space through which the wedge moves in the direction \( BC \) by \( x \), we have, substituting for \( s \) and \( f \) their values, and for \( V \) putting its equivalent \( 2g h \), where \( A \) is the height due to the velocity \( V \),

\[ x = \frac{t^2 v}{2g} \frac{\sqrt{Q}}{P} \]

\[ x = \frac{t^2 v}{2g} \frac{\sqrt{Q}}{P} \]

The values of \( m \) and \( n \), that is, of \( t \) and \( v \) may be found, since \( e \), the modulus for iron, is known to be about 10,000,000 feet; and consequently the relation between \( m \) and \( q \) can be determined in numbers.

WEDGEWOOD, Josiah, was born on the 12th of July, 1730, at Burslem, in Staffordshire, where his father, Thomas Wedgwood, and some other members of his family, were engaged in the manufacture of pottery; a branch of industry then in so very imperfect a state that, independent of the supply of porcelain from China for the use of the higher classes, England imported large quantities of porcelains, and various kinds of earthenware from France, Holland, and Germany, for domestic use. His education was very limited; and the low social position of the class from which he sprung is implied, rather than distinctly expressed, by the local historian, Simon Shaw, who remarks that scarcely any person in Burslem learned more than mere reading and writing until about 1750, when some individuals endowed the free-school for instructing youth to read the Bible, write a fair hand, and know the primary rules of arithmetic. The little opportunity that Wedgwood had for self-improvement is further indicated by the circumstance stated by Shaw, that at the age of eleven years Josiah worked in his elder brother's pottery as a thrower, his father being already dead. In the small-box, which left an indelible lameness in his right leg, so as afterwards to require amputation, compelled him to relinquish the potter's wheel. After a time he left Burslem, and entered into partnership with a person named Harrison, at Stoke; and during this partnership, which was soon dissolved, his talent for the production of ornamental pottery was developed itself. He then became connected with a person named Heidleon, with whom he manufactured knife-handles in imitation of agate and tortoiseshell, melon table-plates, green pickle-leaves, and similar articles. The manufacture was developed into porcelain and other departments of the pottery business, and was unwilling to embark in the new branches for which Wedgwood had so great a predilection. Wedgwood therefore returned to Burslem in 1759, and set up for himself, in a small chamber above his factory, where he conducted his experiments, and which he afterwards made a complete table of ornaments as are mentioned above. His business was prosperous, he soon took a second manufacture, where he made white stone-ware, and a third, at which was produced the improved cream-coloured ware by which he first took notice. As a result, he found, a valuable commodity for his wares, who had worked a considerable pottery, retired from business, but he continued industrious and persevering, 'and certainly,' observes Shaw, 'there was room then for such a person, in a manufacture gradually rising into celebrity; assisted in what branches he pleased, he could, in all probability, have established a new manufacture.'

Of the new cream-coloured ware, of which an account is given under Earthenware, vol. ix., p. 243, Wedgwood presented some articles to Queen Charlotte, who thereupon ordered a complete table service, and was so much pleased with it as to appoint him her potter. Several other kinds of ware invented by Wedgwood are mentioned in the article above cited, where also is given a quotation from the 'Travels' of Faujas Saint FOND, which shows how widely the name of Wedgwood's pottery spread before the time at which the traveller wrote, about the commencement of the French revolution. Wedgwood opened a warehouse in the metropolis, at which the productions of his ingenuity might be freely inspected, and in his partner, Mr. Bentley, who managed the London business, he found a valuable and adjutor, whose extensive knowledge in many departments of literature and science, and acquaintance with many eminently skilled men, greatly assisted him in the higher branches of his manufacture, and especially in obtaining the best specimens of sculptured, painted, gilded, or charged, medals, medallions, and seals, suitable for imitation by some of the processes he had introduced. Some persons trusted to valuable sets of oriental porcelain for the like purpose; and Sir William Hamilton lent specimens of ancient art from Herculaneum, of which Wedgwood and his numerous workmen produced the most accurate and beautiful copies. While Wedgwood was prosecuting these branches of his art, the portrait or Barberini Vase was offered for sale, and, considering that many persons to whom the original was so unattainable might pay a premium for a copy at a price for a good imitation of it, he endeavoured to procure it, and for some time continued to offer an advance upon each bidding of the duchess of Portland, until at length, his motive being ascertained, he was offered the lease of the right of withdrawal of opposition, and consequently the duchess became the purchaser, at the price of eighteen hundred guineas. Shaw states that Wedgwood sold the fifty copies which he subsequently executed at fifty guineas each, but that his expenditure in producing them is said to have exceeded the amount of the sum thus obtained.

According to Allan Cunningham's ' Lives of the most eminent British Painters, Sculptors, and Architects ' (vol. iii., p. 258), Flaxman was one of the artists employed by Wedgwood to design pottery patterns, including a plate on which he depicted the Judgment of Paris, an art which he was the first, in modern times, to execute in pottery. By numerous experiments upon various kinds of clay and colouring substances, he succeeded in producing the most delicate cameos, medallions, and miniature pieces of sculpture, in which he adapted a substance which was adapted to resist all ordinary causes of destruction or injury, that they appear likely to exceed even the brooches of antiquity in durability. Another important discovery made by him was that of painting on vases and similar articles, without the glossy appearance of other porcelain or earthenware; an art which was practised by the ancient Etruscans, but which appears to have been lost since the time of Pliny. The indestructibility of some of his wares rendered them extremely valuable for the formation of chemical vessels, particularly those exposed to the influence of acids. The fame of his operations was such that his works at Burslem, and subsequently at Etruria, a village
erected by him near Newcastle-under-Lyme, and to which he entirely removed in 1771, became a point of attraction to numerous visitors from all parts of Europe.

The result of Wedgwood's invention was not only obtained for him extensive patronage and ample fortunes, but were also of the highest importance to the commercial interests of his country. Almén observes that his new wares, his improved forms and shafte style of decoration, and the new materials, should be equally applied, were chiefly executed by artists of his own forming, turned the current in this branch of commerce, while the national taste was improved, and its reputation raised in foreign countries. His inventions, says this writer, 'have prodi-
giously increased the revenue of the country, and which shew that there is a demand for potters, and in the traffic and transport of their materials from distant parts of the kingdom; and this class of manu-
ufacturers is also indebted to him for much mechanical con-
tributions, principally in the arrange-\mnent in his operations; his private ma-
ufactory having had, for thirty years and upwards, all the e\nc\ff\acy of a public work of experiment'. In evidence before a committee of the House of Commons, in 1765, Wedgwood stated that from 10,000 to 20,000 persons were the first employed in his manufacture, and much greater numbers in digging coal for their use; and in various and distant parts of England, and even Ireland, in raising and preparing flint and clay for the earthenware manufacture; 40,000 or 60,000 tons of those materials being annually imported and readily exported, which involves a considerable navigation. The importance of the manufacture which he had so materially assisted in raising to this prosperous state is further illustrated by the statement that although many of the states of Europe had prohibited the admission of British manufactures, yet the annual exports of earthenware to mineral countries, for the purpose of being manufactured into a quantity of goods, totalling five-sixths of the quantity made were exported. Wedgwood's success also led to the establishment of improved pottersies in various parts of the continent of Europe, as well as in several places in Great Britain and America.

In addition to the attention bestowed by Wedgwood upon the manufacture with which he has inseparably connected his name, he deserves remembrance for the public spirit displayed by him in the encouragement of various mechanical concerns. By his advice and skill of Bredley a navigable communication between the eastern and western coast of the island was completed, by the formation of the Trent and Mersey Canal, for which he cut the first sod on the 29th of July, 1766, and which was completed in 1770. By means of this undertaking and in water-communication was established between the pottery district of Staffordshire and the shores of Devonshire, Dorsetshire, and Kent, whence some of the materials of the manufacture were imported, and many benefits were afforded for the exportation of the finished articles. Wedgwood also planned and carried into execution a turnpike-road, ten miles in length, through the Potteries. He was the founder and one of the principal leaders of the association for the preservation of the bacon hogs, which is called by many in all parts of Great Britain, instituted in consequence of Mr. Pitt's pro-
positions, in the year 1768, for adjusting the commercial intercourse between Great Britain and Ireland; an associa-
tion by whose prompt and energetic interference most serious evils were averted from the manufacturing interests of this country, and whose proceedings upon the subse-
cquent occasion of a commercial treaty with France, pub-
ished in the Appendix to Almon's 'Aneodeses,' contain some curious information respecting British commerce and manufactures.

Wedgwood's pyrometer is fully noticed elsewhere. [Pyrometer, vol. xix., pp. 164, 165.] He was a fellow of both the Royal Society and the Society of Antiquaries, and, as noticed in the article owed to, contributed some papers to the Philosophical Transactions. In his character he is said to have been exemplary, and to have made the most liberal use of the ample means which his successful and honourable career placed at his disposal; but authorit\ty and singularly deficient in respecting his past social history. He died at Mursie, where he had erected a handsame mansion, as well as manufactories and residences for his workmen, on the 3d of January, 1795, in his fifty-fifth year.

Censure of the county of the Staffordshire Pottery, published at Hanley in 1829; 190-194; Maeperson's Annals of Commerce, iii., 381-386; Almon's Biographical, Library, and Political Anecdotes, ii., 164-174; Gentleman's Mag-
azine for January, 1735, p. 84.

WEEDON. [Northamptonshire.]

WEEDON BECK. [Now Warwickshire.]

WEEDON. Every plant which grows in a field other than that of which the seed has been sown by the husbandman is a weed, and, in as much as it interferes with the intended cultivation, and reduces the quantity of harvest, it is prohibited by law. If the husbandman permits the initial cultivation, when few seeds appear amongst the growing crops; and many of the operations of tillage are intended chiefly for their destruction. One of the principal uses of summer fallows is to destroy the weeds, which come up in the winter, and which their roots were not destroyed before the seeds ripen. When roots are sown in drills and carefully hoed, they produce the same cleansing effect, and supersede the fallow: but in heavy loams which have been neglected and overrun with weeds, a clean fallow is a farce indescribable, before any improved method can be adopted. When a farmer enters on lands which are in a foul state, it is the cheapest way, in the end, to sacrifice a crop and thoroughly purge his fields from weeds, especially those which are preci-
ous; and cannot be exterminated by simple ploughing. The mode of doing this must depend on the nature and duration of the weeds, whether their roots are perennial or die off after the plant has borne seed. Annual weeds are burned as soon as they are perfect; while weeds, which the seeds are brought within the influence of the atmosphere and when they have fairly vegetated may be buried or rooted out, and by exposing their roots to the influence of a hot sun they are effectually destroyed. The seeds of annual weeds, grown on the manure, are also destroyed, which is made in the yards, where the cattle fed on hay or straw swallow the seeds, which pass through them undigested. By exciting a great degree of fermentation in the mixture of dung and litter some of the seeds may be de-
throned, but many will remain thus protected, and even after having been exposed to a considerable heat: and, as it is not advisable to let the manure undergo a great degree of decomposition before it is carried on the land, many seeds always escape destruction, and vegetate as barny as they are buried in the yard, which are buried deep lie dormant for a long time, and vegetate as soon as the plough brings them up again.

The experienced farmer knows well what peculiar species of weeds infest his fields, according to the temperature and order of the three seasons, and by studying their habits, time of flowering and of ripening their seed, he learns the best mode of destroying them.

One of the great advantages of composts made with human excrements mixed with earth and mineral sub-
stances is, that they introduce no weeds into the soil. It is reported that in China, where the dung of cattle is little used, in comparison with human excrements, no weeds are to be found in the fields: and if more attention were paid to the preservation of human excrements by feeding cattle and horses, that the ploughs, which are buried deep lie dormant for a long time, and vegetate as soon as the plough brings them up again. Feeding sheep on roots and corn, while they are folded on the land, is another mode of manuring a field, without introducing weeds, especially if no hay is given them, except clover-hay of the second crop, which is generally most free from the seeds of weeds. It would be impossible to enumerate all the various weeds which may infest our fields. This would be giving a flora of all the British woods; but we will state the most common and troublesome to the farmer, with such an account of each as may suggest the most ready means of destruction.

Of the annual weeds we may mention the following noticed by Professor Low in his elements of practical agri-
culture.

Sinapis arvensis, or Wild Mustard, usually called char-
lock, is a weed the seeds of which being of an oily nature will remain dormant in the soil for an indefinite time, if buried and covered with surface-soil; but after the first deepening their ploughings, which otherwise would be very advantageous, because they have found that, in some soils, a ploughing beyond six inches deep will cause the crop to be overrun with charlock so as to choke it out, and to bring about the competition, and an outlay, which will be well repaid in the end, to destroy this enemy. Hoed crops will destroy the plants as they come.
up. Winter tares may be cut before the charlock
perfects its seeds, will help to destroy it, and if they are
succeeded by turnips there will be little charlock left in
autumn. Where it appears and the yellow flowers it
must be pulled out, whatever be the cost, and care
must be taken to carry the plants out of the field to burn or
rot them; for the seeds will vegetate when they are but half
ripe in the pods. We have dwelt at length on this weed,
because it is so troublesome. We may lose most of our best soils,
and which must be eradicated before the land can be properly
cultivated.

Somewhat allied to the last is the wild radish, Raphanus
rospertus, which is also called charlock,—the mode of
destruction is the same.

Papaver Rhoeas, or Corn-Poppies, infects some soils in
particular seasons. If the seed is allowed to ripen and
shovel it will increase rapidly: good tillage however soon
destroy them;: clover and rape which are cut while the poppy
is in flower generally eradicate it. In some seasons it will
appear in great profusion, and in others not a plant will be
seen.

Cleavers Cymenus, or Blue-Button, is seldom found in
any quantity, except where there is a slovenly culture, or
two white crops are taken in succession, a practice which,
it is hoped, will soon be obsolete.

Chrysanthemum segetum, Corn-Marigold, infects some
soils with a sprinkling of seed each season; where the
wheat is drilled, this is a difficult task.

Pyrethrum inodorum, Corn-Feverfew, often called
Mayweed, as is the wild chamomile, often infects the
crops of corn, and with every care it is seen somewhere in
the fields. We have observed generally, that where the corn is reaped by the sickle and a
long stubble is left, the seeds of weeds remain on the land,
and although some of them are eaten by birds, yet
many are ploughed in after the stubble has been raked off
again. But if the crop is mown or cut close to the
ground, which is called mowing or bagging it, all
the weeds are tied up with the corn and go into the barn or
stack: and if care be taken in the winnowing and sifting
of the grain to separate the smaller seeds from the straw
and bran, the latter which often will be clean and
strong and of the cattle will contain no seeds of weeds. This
is by far the best mode of proceeding; and by careful hoeing
and weeding and burning the small seeds, the land may be
kept tolerably free from seed-weeds.

The Bow-Thistle, Sonchus oleraceus, often raises its
head above the corn. The seeds are blown about by the
winds, and if the hedges and headlands are not kept clear of
these, they will sow themselves in all directions; but it is
evitable, and easily controlled by the hand, and by middling
its flower expands. To destroy thistles in general, it is
only necessary to cut them down just as the flower is
expanding; the roots will then die, and in a few years, by
the united attention of the farmers in a district, thistles may
eventually be destroyed. In some places, where they are
employed in pulling up all the thistles in the hedges
which border the roads, and wherever they make their
appearance in the highways and lanes of a parish. This
practice cannot be too generally recommended, for the
hedges and ditches on the sides of roads and lanes are
often perfect nurseries of weeds.

Arctium Lappa (Burdock), is a very common weed in
fields; but with a little care it is easily extirpated.

Tansy, or Corn-Tansy, is a very injurious
weed, because its seeds ripen about the time of the
harvest, and from its size cannot be easily separated from the
corn by sifting; it contains a paria which is oily and when
ground with the corn greatly deteriorates the flour. The
ordinary action of lime on the crops and early hoeing them is the best means of destroying this
weed; as soon as the crop gets above the chickweed, it is
soon destroyed, if the latter covers the ground well. It
often does harm to young clover, but the latter soon
overpowers it. Tares another important weed. The same
precautions are applicable to the Spergula arvensis, or Corn-
Spurrey, a larger variety of which however is cultivated
as excellent food for milk cows.

Galium aparine, or Goose-Grass, also called Cleavers,
is a weed which is dispersed by the seeds attaching
themselves to the wool of sheep by means of hooks with
which they are provided. The thorns thus附着 is seldom
if they are not carefully pulled up and the heads cleaved of
them.

Urtica urens, Stinging Nettles, generally grow where
the ground has been strongly manured, especially when
been dung has been laid on immediately after the
stroke and are easily eradicated by repeatedly ploughing, and
insect gardens more than fields.

Polygonum Convulvulus, Climbing Buckwheat, is a
very troublesome weed, which makes the ground round the
corn and often overtops them. The seeds are said to
be nutritious and not to injure the oats when mixed with
them; but in wheat it is very destructive, and diminishes
the product while it injures the quality of the corn.

All the charming grasses are weeds. In some cases, and
in the alternate husbandry are introduced in the regular
cultivation. When the grass is ploughed up, if the seeds are
not covered sufficiently so as to rot, tufts of grass remain
which greatly increase to the injury of the next crop.
However carefully the land may be ploughed, if it be sown
immediately, the roots of grass will be raised to the surface
by the harrows. The only remedy is to have them care-
fully forked out, and carried to some corner or waste ap
loft, or to burn them during ploughing or harrowing.
When the land is ploughed up before winter and the seed
sown in spring, the grass will be rotten and have lost its
vegetative power.

The Bearded Wild Oat, Avena fatua, is a very trouble-
some weed, especially in corn fields. The truth of the
out is quantity: but this can only be the case with very slovenly
farmers. It ripens sooner than the corn and sheds its seeds
before harvest. Crops cut green for fodder, such as rye,
winter barley, and tares, repeated if necessary, soon destroy
the seeds and make it easy to eradicate them.

These are some of the most common annual and
biennial weeds. They may all be easily destroyed by weeding
at the time when they have pushed up their seed-stems
and the flower is about to expand; if they are cut up at
the time when they are clean and young, unless the weather be dry enough to scorch the
roots exposed, often increase them instead of killing them.
But the last-mentioned weeds are easily got rid of in
comparison with those which come after the corn, and
some of which increase the faster the more the roots are
divided. It may be proper to observe that too little
attention is paid to the weeds in our upland meadows
and pastures. One would imagine that every plant which
appears in the meadow is injurious. When young, unless
or when the weather be dry enough to scorch the
roots exposed, often increase them instead of killing them.
But the last-mentioned weeds are easily got rid of in
comparison with those which come after the corn, and
some of which increase the faster the more the roots are
divided. It may be proper to observe that too little
attention is paid to the weeds in our upland meadows
and pastures. One would imagine that every plant which
appears in the meadow is injurious. When young, unless
some weeds are used by the cows, the cattle may be very injurious
in the meadows; and even in mountain meadows, where the
grass is wholesome for cattle, whereas many are detri-
mental when they are eaten for want of better food. Of
this kind are the ranunculus, commonly called butter-cups,
which, far from deserving this name, are never touched by
the cows. The butter-cups pluck some parts of the grass,
but the roots of these weeds are all hidden in the
soil, and the length of ascribing to the butter-cups the power
of causing epidemic diseases in cattle, and even in
people who eat of the milk and butter of cows who have eaten
them, there is no doubt that where the cows are forced
by hunger to eat many of them, they may be very injurious
to their health and to the production of good milk. As these
plants have strong perennial roots, they take possession
of rich moist soils to the exclusion of good grasses.
But the abundant the plants may be killed off in
autumn, the experience will be well
repaids in the quality of the hay or pasture. Where
they are very abundant the only remedy is to break up the
grass in autumn, let it be exposed to the frost in winter,
and the crop of corn next season, and the grass will
be grown up the after. In the succeeding spring the land may be
inoculated with good tufts of grass, and before the next
year an improved pasture will have been formed: or, if
this is too much trouble, it may be summer-followed and
by the turnip or barley. As already mention above, the crop of the
it is expensive, as a whole year's produce is lost, but the sub-
sequent pasture will be so much better, that the expense
may be considered as a profitable investment. The most
common species of butter-cup are the Ranunculus arcti,
R. acris, and R. ficaria. R. arcti is poisonous; but not common, except in marshy pastures.
Sanecio Jacobaeus, or Rag Wort, is another troublesome
weeds: but as sheep eat it readily when young, it is easily
kept down by pasturing and folding. In moist weather also it is easily pulled up by hand.

**Tussilago farfara**, Coltsfoot. By its large leaves it kills the finer grasses under it, as moisture is essential to its luxuriance, drainage tends to diminish its growth, careful manures also make the grasses get the better of it, and choke it when young.

**Chrysanthemum Leucanthemum**, or Great White One Eye, sometimes abounds in inferior pastures, and is only extirpated by pulling the plants up by the roots and burning them. It is differing the height of man and beast, and may both be eradicated, but the means employed to get rid of the clover grass will work against the growth and most other perennial roots. These troublesome weeds may have been wisely dispersed through the soil by Providence, to induce the cultivator to give his land a more thorough cultivation, but without the expense of forking, and what is usually called couching, is generally simply repaid by the finer tillth it gives to the land, and the crops are more certain and abundant in consequence.

There are many other weeds both in arable and pasture land which indicate slovenly culture, and which disappear on careful cultivation: such are briars, furze, broom, and rushes; the last being a well-known sign of superabundant moisture, and only to be destroyed by under-draining. The introduction of the thistle is to be deprecated, but the means employed to get rid of the clover grass will work against the growth and most other perennial roots. These troublesome weeds may have been wisely dispersed through the soil by Providence, to induce the cultivator to give his land a more thorough cultivation, but without the expense of forking, and what is usually called couching, is generally simply repaid by the finer tillth it gives to the land, and the crops are more certain and abundant in consequence.

**Week** This well-known period of seven days, now universally adopted over the Christian and Mohammedan world, appears to be of Hebrew or Chaldian origin. It is so described as a measure of time, which was the period of the world, according to the Mosaic account, in that space of time; but it is besides the most obvious and convenient division of the lunar or natural month; and it is more nearly short than any other period would be, an aliquot part of the solar year of 365 days; so that its commodiousness in these two ways would seem to have been sufficient to recommend its adoption.

**Dion Cassius** attributes the invention of the week to the Egyptians, from whom he seems to say it was borrowed in later times by the Greeks and other nations (Hist. Rom., xxxvii. 18, 19, and the note in Reimar's edition).

The assertion which is sometimes made, that according to Herodotus the Egyptians had a week of seven days, or any other number of days, is a mistake. He simply says (Hist. 82) that the Egyptians invented the month, and assigned each day to some deity. It is certain that the week was unknown to the Greeks of the classical ages, and also to the Romans, till it was gradually adopted, along with Christianity, under the later emperors. The curious passage we have referred to in Dion Cassius is the source of all that is known as to the origin of the names that have been given to the days of the week. This female heathenism, which dates its origin from the time when the earth was separated from the firmament, is in this order: Jupiter, Mars, the Sun, Venus, Mercury, the Moon, the Earth (being the most distant); and it was a primitive and ancient astrology that these planets presented the symbols of the respective hours of the day. Thus to the first hour be assigned Saturn, it will be 25th (or first hour of the second day) 7th (or first hour of the first day) 14th (or first of the fourth day) to Mars; the 49th (or first of the third day) 28th (or first hour of the second week) 119th (or first hour of the seventh day) to Jupiter; and the 140th (or...
to Venus. 

**Dias Saturni** (the day of Saturn), **Dias Solis** (the day of the Sun), &c., are, accordingly the Latin designations of the days for which the positions giving to the day of the week, and from these have been formed the modern names used in different countries, either by literal translation (in the Italian, Spanish, French, and other languages of the Latin stock) or by shortening, as, in a few cases, for the classical god of the corresponding deity of northern paganism. Thus the deity of the Old Saxons most resembling Mars being held to be Tiw, or Thu, the day of Mars was called by them, after their conversion to Christianity, **Twee dag**; whereas our Tuesday and probably also the modern German Dienstag; for a similar reason the day of Mercury received the name of Wodnes dag (that is, Woden's day), whence our Wednesday (and the old German Odinstag, for which Mittwoche, Mid-week, is used); the day of Jupiter, **Donnes dag**, or Thor's day (whence our Thursday, and the modern German Donnerstag); and the day of Venus, **Frige dag**, or Friga's day (whence our Friday).

Dion Cassius however further states that the planetary names, as they were denominated, the names of the days of the week have thus been derived is itself founded upon the doctrine of musical intervals. A highly curious exposition of this idea has been given by the Abbé Roussier, in a Memoir on the Music of the Antients, printed in the *Monthly Magazine* for November and December, 1770, and August, 1771.

It is a remarkable fact that the week of seven days is not only a recognised space of time in the ancient Brahminical astronomy, but that the days (beginning with Saturn's brightest star being its sun) are correspondingly named as to correspond to the seven planets or gods, in order of course from the most distant to the nearest. There are only a few instances of the month of Venus, and in succession after the same planets or heavenly bodies as among the Greeks and Latins. Upon this subject see Baily's *Astronomie Indienne et Orientale*, and various papers by Mr. Colebrooke and others in the * Asiatic Researches*. The subject of the week in also discussed by Bohlen, *Das Alte Indien*, ii. 214.

**WEEVinX, JAN BAPTIST**, called 'the Old,' a distinguished Dutch painter, who excelled in almost every department of his art—his portraits, animal pieces, landscape, and marine painting. He was the son of Jan Weeninx, an architect of Amsterdam, where he was born in 1624, but lost his father when very young. He was first apprenticed by his mother to a bookseller, but he so professedly neglected everything except drawing, that his mother placed him first with a painter of the name of Jan Micker, and then with Abraham Bloemaart at Utrecht, with whom he soon made great progress: he studied afterwards two years with Nicolas Molenaer, and acquired his style of painting from him. At the end of eighteen months, married the daughter of the landscape-painter Giles Hendekoker, the grandfather of Melchior Hendekoker. Four years after his marriage he went alone to Rome, intending to remain only a short time there; but his own inclination, strengthened by his reception into the cardinal's family, and others, prolonged his stay there four years, when he was compelled by the importunities of his wife and friends to return to Holland. He died at Utrecht in 1660, aged only thirty-nine. Weeninx painted in large and square openings, and in his execution. In a single summer's day he painted three half-length portraits of the size of life, with accessories. Some of his small pictures are very highly finished, but his large works have more merit. He was one of the best painters of birds of the Dutch school. Weeninx's principal pieces of great merit by Weeninx, the Prodigal Son, commonly called *T Pissend Jongertje*; it has been engraved in mezzotint by N. Verkolje. There is a clever etching of Weeninx's Houboken's work, after a portrait by Batt. vander Heel.

**WEEVinX, JAN**, called 'the Young,' was the son and pupil of Jan Baptista Weeninx, and painted in the same style and the same subjects as his father, whom however he leaves behind him nothing of the best painting and sporting pieces, and also surpasses in colouring. He was born at Amsterdam in 1646, and after spending some years in the service of the elector John William of the Pfalz, he returned to his native place, and died there in 1710. Jan Weeninx painted likewise in China, and, like his brother, with great care. There are many excellent large pictures by him of birds and hunting-scenes in the gallery at Schiessenheim near Munich. (Houboken; Descamps.)

**WEwvil** is the name popularly applied in England to the beetles which resemble *Colesuilo* or Limmexus, now the type of a large family of coleopterous insects, distinguished by the prolongation of the head so as to form a sort of snout or proboscis. The weevils are favourites with the entomologist on account of the singular character of the head, and their parasitic habits. One splendid diamond beetle, the wing-cases of which furnish such gorgeous microscopic objects, is a member of the tribe. Many of them are adorned with the most vivid metallic lustre, and some in intensity and brightness of hue equal the beetles of the Orient. Weevil larvae often perpetrating serious mischief. Their natural history therefore has been made an object of special researches in the hope of counteracting their ravages. We shall here give some account of the numerous species.

**Weevile attacking the nutritive organs of plants.**

The *Rhynchos Betula* is a little blue or green beetle, glistened with metallic lustre, which attacks the vine and the pear-tree. It is four lines in length, one-third of which is occupied by its snout, and is able to disfigure and dismagnis the male from the female. It attacks the leaves of the plants mentioned, in order to construct its habitation of them, and with a view to their furnishing food for its young. It rolls up the leaf into a tube, and in this the eggs are placed. When the tubes are hatched, the nest is afterwards supplied by the larve with food. As the maggot grows, the rolled leaf and its stalk dry up, and at length fall to the ground on the first high wind, by which time the maggot is fully grown and ready to leave its house, bury itself in the ground and wait for the spring, when it is to appear in a new garb as a weevil.

The process by which the roll is made is thus described by KOLLAUR: 'When the female has selected a suitable leaf, which may not be of any particular kind, so that it hangs down and is more conveniently placed for future proceedings. She then begins to roll the leaf together, generally alone, but sometimes assisted by the male. While this operation is going forward, she also lays her eggs, that is, she picks up through the opening, and pushes it in with her rostrum, in such a manner that it remains on the inner side of the leaf. When she has introduced five or six eggs in this manner, between the different folds, she rolls the remaining part of the leaf enclosed, so that the maggot shall have room to extend and roll up. The egg is then shown to have an outward appearance, in what manner the eggs were deposited.' This beetle is externally injurious to vineyards by defoliating the vine, after which the grapes will not ripen, and the prospect of a vintage is destroyed. The rolled-up leaf is commonly considered to be the caterpillar, which is destroyed before the worms have time to arrive at maturity. Its operations are often erroneously ascribed to *Rhynchos Batitus*. The *Olitorhynchus salicatus* is another beetle which is injurious to the vine by gnawing off the young shoots. It also attacks the roots of succulent plants.

**Neuocoris oblongus** is a little weevil only two lines long, with a very short beak, a black head, body, and thorax, and reddish antennae, feet, and wing-cases. It attacks the young leaves of young fruit-trees, above all those of the peach. Its larva is as large as a nut, and, being most voraciously, it selects only the delicate portions of the leaf, the cellular parenchyma, leaving the midrib and petiole untouched. It appears very early in spring, and after pairing the female deposits her eggs in the ground, the grub feeding on the roots of various plants until the following spring. When these insects are on the trees, they must be gathered with the hand.

There is a very small species of *Rhynchos*, the *R. alliaceus*, a line or two long, very small, and of a blue or green colour, by which, injuring the shoots of young trees and fine grafts, is a source of great annoyance to the planters, sometimes perpetrating great ravages in nurseries, without distinction as to the kind of trees. The principal subject of all his subsequent account of the operations of this insect is extracted from KOLLAUR:

'When the shoot of the tree or graft is about a span long, the female selects one that suits her, and it does not signify...'

Digitized by Google
to what kind of fruit-tree it may belong. As soon as she has reached the most suitable part of the shoot, she marks the place first by a prick or by a small cut, where she intends to cut off the bud. Thus the weevil then proceeds along a line upwards, and begins (with her head turned downwards) on the side which is not next the tree, to bore with her proboscis until she reaches the middle of the shoot. With it she also widens the channel and prepares for herself other entrances. Then, when the insect is certain, it lays an egg, which is pushed in by the proboscis and conveyed to the proper place. This operation lasts an hour. Immediately after the female returns to the former place, to cut off the shoot, moving it from one side to the other while she works, she immediately proceeds to destroy the finest apple-blossoms to be the candles of its offspring. It bores a hole in them with its proboscis, making a canal even to the parts of fructification; then laying its eggs at the circumference, it turns the bud and pushes it in with its snout as far as it can. This operation it repeats for every egg. The eggs lay, walking from blossom to blossom, choosing the finest and calmest days for its labours. Nothing but gathering the beetles and destroying the affected flowers will arrest their progress; and by doing so we may diminish their number, though, it is to be feared, hopes of their extirpation are vain.

There is another weevil of the same genus, the Antho-
nomus petri, very similar in appearance, which destroys both blossom and leaf-buds of the pear, and which, when not too numerous, may even increase the crop by preventing an overweight of fruit. The ascent of both these beetles up the trunks of the trees may be impeded by circles of papers covered with tar.

The beetle is destroyed by a weevil called Rhynchites curvipes, which sometimes also makes use of the soft spring shoots of plum and apricot trees. The female beetle attacks the plums when they are about the size of almonds. She has two objects in view: first, to destroy the trees, and secondly, the eggs-laying operation is completed she severs the stalk altogether; the joint operations occupy from two to three hours. It takes the grub five or six weeks to devour the pulp of the plum. If left undisturbed, the beetle never leaves the tree until it has pierced and thrown down every plum it can find. The only remedy or preventative of its destructive industry is to gather and destroy the affected branches, which can be easily done on the apple by another species of Rhynchites, R. Bacchus, the hue of which is beautiful purple and gold.

In the first volume of the 'Transactions' of the Entomo-
logical Society, Mr. Curtis describes a weevil called the Calandra tamariindi, which destroys tamarind stones. There are sometimes thirty or forty of these weevils in a single stone. He was led to seek for them from finding that the stones of tamarinds sometimes crumbled to pieces beneath the mouth. In the course of his inquiries, he observed that the affected stones were coated on the apple by another species of Rhynchites, R. Bacchus, the hue of which is beautiful purple and gold.

WEH

States, towards the beginning of the last century, the cultivation of peas was abandoned in consequence of its ravages.

Tacitus, On Insects injurious to Farmers; Agricultural Journal; and the works cited.)

WEHRGELD, or WEHR (in Latin 'Wergeldum,' and in some cases 'Composition'), was a kind of fine for manslaughter, wounds, &c. in use among the ancient Teutonic nations, by paying which the offender was absolved from every further obligation or punishment. The punishment of death was almost unknown among the Teutonic nations, and was never inflicted for crimes against individuals, but only for crimes and misdemeanours by which the community was injured. Tacitus observed, that traitors and deserters were hanged on trees, and that cowards and such as were of infamous lives (corporre infames) were mangled in marshes; hurdles were thrown over them, by which their bodies were beaten to death. Several bodies of Germans, who were buried in that way, with the hurdles still over them, have been found in the great marshes of Northern Germany. It is very likely that death inflicted for such crimes was 'less a punishment than a means of getting the wehrgelde for the community, and for whom there were no prisons. Crimes committed by one individual against another were considered not directly to concern the community. The wounded man, or the relations of him who had been slain, pursued and hanged on trees if they found them guilty for satisfying their vengeance by giving them a certain number of cattle and arms. (Tacitus, Bk. 21.) If the parties belonged to different communities, the consequence was a feud between them and their adherents, no community having the alms of kindred. In another case the parishes belonged to the same community, the matter was soon settled. The plaintiff called the offender before the community, and if the defendant was found guilty, he was sentenced to pay a certain fine, the wehrgelde. If the defendant would not or could not pay, his relations were bound to pay for him; the father paid for his children, the master for his serfs, and he who received a stranger in his house was liable for the misconduct of his guest. The plaintiff was entitled to recover the fine paid by the offender before the meeting: he could pursue his cause with his sword, and thus compel the defendant to pay the wehrgelde, which was always proportionate to the offence. If the cause was brought before the community, the plaintiff only received part of the fine, the rest being considered as a fine for the breach of peace, and the consequence of the reciprocal obligation of the members of the community to mutual aid.

We learn from the written laws of the Teutonic nations that the wehrgelde was for various crimes and misdemeanours, such as murder, manslaughter, inflicting of wounds, and grievous bodily harm, robbery, theft, incendiarism, plundering, forgery, and other crimes against the person, and others, such as the violation of a grave (Lex Salica, tit. xvii.), by which is understood not only the injury done to the tomb, such as taking the tombstone from one grave and putting it upon another, but also slaying a dead body, or its clothes and ornaments. The general Latin name for the fine paid for such crimes is 'compositio;' wehrgelde designating merely the fine for a crime committed against the person of a freeman. The amount of the fine was in proportion to the crime, the loss of an arm, for instance, being proportionate to the loss of the hand. The murderer, or person who caused the death of the person, was guilty of a heavegelde, which was paid by the relative of the dead in proportion to the damage and the harm caused. The punishment of death was ordered if the murderer, or person who killed, would not or could not pay the fine.

The following is a short view of the system of the wehr- gelde according to the 'Lex Salica,' which is one of the most important of the ancient Teutonic laws: the change in the order of the titles has been made for obvious reasons.

Tit. xlvii., De Homicidio in Compositio:—He who kills a Frank, or a barbarian entitled to the benefit of the Salic Law, pays 8 denarii, or 200 solidi. If he has thrown him into a well or drowned him in water, 24 denarii, or 600 solidi. If he has lived with him under the same roof 24 denarii, or 600 solidi. If he has taken his property 40 denarii, or 1000 solidi. If he has beaten him, 800 solidi. If he has driven him out of his house, is 600 solidi; if he is murderer, 1200 solidi, with a heavegelde of 200 solidi. If there are several murderers, each pays the same fine, and each is responsible for the other. Tit. xlv., De Homicidio in Convito factis:—If there are less than seven persons present, they must either name the culprit or pay collectively the wehrgelde; if there are more than seven, inquiry is made, and the culprit alone pays, if he is detected. Tit. xxxvii., De Homicidio Servorum vel Ancilariarum:—If one servile or a master agrees upon the wehrgelde the serfs are subject to corporal chastisement. If the servant is a freedman, the master only pays the defunct. Tit. xxxv., De Poenis, He who has attacked a freeman, but failed, pays 62 solidi: for beating a man on his head, if blood comes and drops on the ground, 15 solidi; for a wound in the head, if three (pieces of) bones come out, 30 solidi; if the brain is laid open and three bones come out, 45 solidi; for a wound between the ribs, if the entrails are touched, 30 solidi; if such a wound will not heal, but keeps open and runs, 62 solidi, and 9 solidi for the doctor; for a slight wound without running blood, 3 solidi; if the blood runs, and the wound is made with an iron instrument, 15 solidi. If the wound runs, 9 solidi. Tit. xxxii., De Dilettatis:—For a foot, an eye, an ear, or the nose, 100 solidi; for a tooth, 15 solidi; for one finger, 62 solidi; for another finger, 3 solidi; for a hare, 6 solidi; he who calls another honest woman a prostitute, pays 45 solidi. Tit. xxvii., De co qui Multari Ingenium Manum strixerit:—He who ties a person's hands, or wounds them, pays 15 solidi; if he puts his foot on the back of a run-wounded man, above the elbow, 35 solidi; if he takes his bosom, he pays 45 solidi, which is the same fine paid for a wound made in a man's head, if the brains are laid open, and three bones come out.

The wehrgelde was not the same among the different Teutonic tribes, as may be seen by a comparison of their laws, the editions of which are given in the history of the Teutonic nations. The laws of the Anglo-Saxons differ in part from the others. (Eichhorn, Deutsche Staats und Reiche Geschichte.)

WEIDLER, JOHANN FRIEDRICH, born at Gross-Neuhausen in Thuringia, April 23, 1691, died at Wittenberg, November 30, 1755. He succeeded Wolff in the chair of mathematics, and was the latter's pupil. There was a number of works, of some of which the bare mention will be sufficient: as, 'Institutiones Mathematicae,' 2 vol., 8vo., Wittenberg, 1718, printed five times at least; 'De Characteribus Numerorum Vulgaribus,' 4to., Wittenberg, 1755; 'Tractatus de Machinis Hydraulicus,' 4to., Wittenberg, 1723 and 1733; 'Institutiones Geometrarum Subtissimae,' Wittenberg, 1751, 2nd ed.); 'Institutiones Astronomicae,' 4to., Wittenberg, 1754.

The works of Weidler is now preserved by two useful works, the 'Historia Astronomica,' 4to., Wittenberg, 1711, and the Bibliographia Astronomica,' 4to., Wittenberg, 1735, of which the latter also contains supplements to the former, and 'Anacreon in the history of Astronomy, was, at the time it was published, the most regular, most authentic, and complete history of a single science which had ever been published; it is to this day a very convenient book of reference, and the more so as it rather should be called the annals of astronomy than the history of the science. The whole work was taken entire by Lalande into his 'Bibliographia Astronomica,' by which work it is therefore supplanted, except for the supplements.

WEIGHING-MACHINE, is any contrivance by which the weight of an object may be ascertained; under the words Balance, Spring-Balance, and Steelyard, the machines by which materials of comparatively small magnitude are weighed are explained; and we have now merely to describe that which is employed usually at the public weights for weighing large weights of produce, like weights of laden carriages. In order to prevent the roads from being too much cut up, the buttens allowed to be
The usual weighing-machine may be described in a general way, as a platform sunk on a level with the road, and made to rest at four points on a double lever of the second kind: the extremities of the arms of these levers rest upon a third lever, which may be of the first or second kind; and this last lever may either serve as a steelyard, or may be connected with one arm of an ordinary balance, or with the extremity of a steelyard.

But to be more particular, let ABCD be the plan of a rectangular pit sunk in the ground, from 8 to 12 feet long, 4 feet broad, and about 2 feet deep, the sides and bottom being lined with brick-work or iron; and let MNRS represent a longitudinal section of the pit perpendicularly to the ground. abed, c'd'e'f are two trapezoidal frames of iron, set as levers; and each of the side bars, as ac or bd, has in the vertical position, the form which is represented by a, a', c', c" in the section. At each extremity a, b, a', b', in the plane, the frames have a conical steel point which appears at a, a' in the section; this rests in a hemispherical cavity made in a die or cylinder of the same metal, which is either attached to the iron-work forming the sides of the pit or is supported on a block of stone sunk in the ground at each of the four interior angles; and under the shoulder of the point of each frame there is a weight of tempered steel having its edge parallel to that side. The ends of these prisms appear at c and c' in the section.

The bar PQ is an iron lever, which in the above diagram is of the second kind, having at P a pin mn, like that of a balance, turning in two steel rings on a pillar of stone sunk in the ground, or of iron resting on the bottom of the box; a steel pin pq formed also like that of a balance, with its edge upwards, passes through the bar PQ; and upon this rest the edges of the prisms at c and c' as shown in the section.

The platform supporting the carriage which is to be weighed, and which is represented at MN in the section, lies below in four iron-feet, of which two appear at X and Y; and the under surfaces of these feet are formed with hemispherical cavities which rest on the points of four conical steel pins at l, m, l', m', on the two lever-frames; consequently the weight on the platform pressing at these four points, the prisms at c, c' are forced down upon the pin pq, and this last then presses down the extremity Q of the lever PQ. This lever itself may be made to act as a steelyard; or, by a rod or chain, the extremity Q may be connected with one arm of a balance or steelyard above the platform, in either case the weight of the carriage may be ascertained.

It is evident, from the nature of the lever, the pressure of the platform itself being balanced by a constant weight at Q, that if W represent the weight of the carriage, the lever PQ will express the weight of Q, or the weight by which that of the carriage is determined: and this is independent of the power obtained by a steelyard which P. C. No. 1704.

\[
\text{If } at = \frac{1}{14} \quad \text{and } Pr = \frac{1}{18}, \quad \text{a weight equal to 10 pounds at } Q \text{ would balance a weight equal to 1 ton upon the platform.}
\]

It is nothing to say on the feeling of weight after what has been said in Pressure; nor is it possible to give any idea which will be half so good as that which presents itself in reality. The measure of weight is weight itself [Balance], and two weights are equal which counterpoise each other when placed at the ends of equal arms of a self-poising lever.

The weight of a body, that is, of a given bulk of known substance, is referred to that of water by what is called the Specific Gravity of the substance. It is said, for example, that the specific gravity of ivory is 1826, that of water is 1000. This means that any body is more weight than the same bulk of water in the proportion of 1826 to 1000. When the specific gravity of water is called 1, that of ivory is 1826. Since a thousand ounces avoirdupois of water are nearly a cubic foot, a more popular notion of the meaning of specific gravity may be given, in this way: To say that the specific gravity of a substance is 1826, that of water being 1, is to say that a cubic foot of it weighs 1826 x 1000, or 1826 ounces nearly. More correctly, from 1000 times the specific gravity (water being 1), subtract three times that of gravity, and add its 73rd part: the last step may be left out for common purposes. Thus, the specific gravity being 4.817, 4.817 x 1000 — 4.817 x 3 is 4922.548, the number of ounces in a cubic foot.

But it is to be remembered, when weight is to be very accurately taken, that every body is buoyed up to a certain extent by the air; and the weight of a body in air is less than it would be in a vacuum by the weight of its own bulk of air. Now the latter varies in weight [Aur] in a manner which may be ascertained nearly by the indications of the barometer. Properly speaking, it varies in a manner depending upon the superincumbent pressure, the temperature, and the quantity of moisture contained in it. A cubic foot of dry air, weighing at sea-level 14.7 pounds, is reduced to 30 inches and Fahrenheit's thermometer at 62°, weigh 31.012 grams. In measuring standards of weight, therefore, close attention must be paid to the state of the air at the time of weighing and to the substance weighed. If an iron weight balances one in the air, then in the vacuum of the atmosphere, for that very reason there cannot be strict equilibrium in any other state of the atmosphere; wood being at least seven times as bulky as iron, the effect produced on the weight of the wood by the alteration of the state of the air is at least seven times as much as that produced on the iron.

WEIGHT OF THE AIR. (Aur.)

WEIGHT OF THE EARTH. This is not the most appropriate name for the body below us, except in the particular, namely, that the position of the letter W has enabled us to await the completion of the experiments which have been lately made for the determination of the mean density of the earth.

The quantity of matter which the earth contains must ultimately be our only guide to that of any other planet. The relative masses of two planets can be found by calculation of the effects which they produce upon any third body; but the mass of a planet with a given substance, as water, cannot be directly determined upon any instance except our own earth. Perhaps a problem could hardly be proposed which would seem more impracticable to the ordinary reader than that of determining the mean density of the earth. It amounts to asking this: If it were required to substitute for the earth a world of the same size, but of uniform material, in such a manner that the absolute weight of bodies on its surface should remain the same, and the attraction of the whole planets remains the same, what would be the density of that body?

Of necessity this question was started by Newton, whose system was the first in which it became of more interest. Having no means of submitting it to experiment, he made one of these sagacious guesses which has been
be collected and preserved, would alone have kept his memory alive. 'Unde cum terrae communissima suprema quassae gravior sit quam aquas, et paulo inferius in fodiens quoddam quadripol vel quadripol aut etiam quattuor gravior super perientur: verisimile est quod copiae materiei tota in terrae quassae quintuplo vel sextuplo maior sit quam si tota ex aqua constaret.' (Principi, iii. 10.) That is, he judged the earth to be between five and six times as massive as the same bulk of water; which is the truth.

The relative masses of two planets are determined by the observation of their effects upon a third. Two preliminaries are required: first, the great assumption of the theory of gravitation, that any two particles of matter must attract one another with forces which at different distances are directly as their masses, and inversely as the squares of those distances; secondly, the mechanical consequence of this law of action, namely, that two spheres, having their centres at equal distances from a third body, attract each other in the same manner as if each were collected in its central. Without describing the mode of arriving at such a result from observation, suppose it is ascertained that two planets, A and B, whose distances from a third are as 4 to 5, attract the earth in such manner that both are brought to the distance 1 from the third, the attraction of the first will be made (4 x 4) or 16 times as great as before, and that of the second (3 x 3), or 9 times. Consequently, the new attractions will be as 7 x 16 to 2 x 9, or in the same proportion as 112 to 18. The second attraction in the proportion of the masses; therefore these masses are as 112 to 18. Now suppose the radii of the planets to be as 3 to 2; then their solidities are as 27 to 8, and if the densities (mean) are 5 and 4, the masses are as 27 to 8. The apparent solidities being thus as 27 to 18 x 27 : 896 : 486. If then the mean density of either planet be known, that of the other can be found.

The principle of the preceding process exists in every apparatus of this nature, which was made to find the mean density of the earth. The earth itself is composed of two planets; some known substance, a mountain or a ball of lead, is made the other planet. The attracted body is not a planet, but a pendulum or a plumb-line, and the effect of the mountain or ball being measured, that of the earth being either measured or previously known. The actual attraction of the mountain or ball being thus determined, its effect as it would be if placed at the centre of the earth can be calculated; which effect is to the effect of the earth as the mass of the mountain or ball of lead to that of the whole earth. The result of this process, as usual, is condensed into a formula, in which the mode of making the steps is lost sight of: but the above is not the less the manner in which the experiment must be carried on.

The hint given by Bouguer, the experiment of Masseleyne, and those of Cavendish and Zach, have been briefly described in Attraction. Since their time two repetitions of Cavendish's experiment have been made: the first, by Mr. Reilly, in 1807, is described in the Philosophical Transactions, p. 92; the second, by Mr. Baily, at the request of the Astronomical Society, and at the expense of the government. The former obtained the same result as Cavendish, but the experiments were few in number; the latter obtained a result slightly differing from that of Cavendish, but in so many different ways and for so large a number of experiments, that it is impossible to doubt the superior correctness of the conclusion. We shall give the results of the second, with some account of the process (which is substantially that of Cavendish) as our limits will allow us to refer to the volume already cited for more detail; very few experiments have been either so well performed or so satisfactorily described.

The large wooden pendulum (76 inches long) was provided, moving on a single or double metal wire, or on a double silk line, the mode of suspension being varied from time to time. At each end was suspended a metal or other ball; and these balls (a and b) were the principal attracted substances. The whole torsion-rod with the suspension was enclosed in a case, with a glass at one end. Large leaden balls (A and B) of about twelve inches diameter (the attraction of which on the torsion pendulum is the quantity to be measured in the experiment) were made to travel on a line so suspended that they could quickly be brought up laterally on opposite sides of the balls, as in the diagram. We must leave out the whole account of the preconceptions against electricity or radiation, the manner of finding the actual position of the pendulum, &c., and confine ourselves to the principle of the experiment.

When a torsion pendulum, such as that described, is left to itself, it never is reduced to absolute rest. The instrument is so delicate that it is continually shifting its direction, so that it cannot be permitted to take a series of observations and make use of them all in determining one mean place. The mode of finding the point of rest, that is, of deducing it from observing the extremes of the vibration, is described in the work cited. The line of rest of a Newtonian pendulum is ascertained, and the large balls are brought into the attracting positions at A and B, on continuing the observation an immediate alteration of the line of rest is seen towards the large balls; say that it becomes nm. Then the observations are the same as if the large balls were altered so that the angle nmO is made, in consequence of the approach of the large balls. The extreme positions of the pendulum, and the assumption of which, as a universal property of matter, led Newton to his explanation of the planetary motions. Many of those who were content to rest on the same as a demonstration, or to explain, say that the pendulum itself must be changed, in consequence of the attraction of the weight.

In making the experiment the effect was usually doubled by placing the large balls first on one side of the smaller ones, and then on the other, thereby altering the whole of the double displacement.

This distance of course was accurately measured.
ball, and its easy consequence, namely, the number of times the whole earth would contain a similar bulk of water: 5. All the necessary corrections for the attraction of the other parts of the apparatus upon the torsion pendulum.

The larger masses were leaden bars, but the smaller balls attached to the torsion pendulum were changed from time to time, and different substances were used. The following table of results will be more interesting than any description we could give in the same space. It shows the results of experiments made after the effects of radiation were removed* by additional precautions. The first column is the number of experiments made, with the small balls and mode of suspension described in the third; the second column is the result of the experiment as deduced from the set of experiments; the third describes the small balls and mode of suspension employed; the numerals, which are fractions of an inch, representing the distance of the suspension wire, when single, and the distance of the wires when double or bifilar.

The results of individual experiments vary considerably, but it is important to observe that there is nothing which indicates that different kinds of matter attract each other according to different laws. If the large ball of lead exerted different attractions upon particles of brass and ivory of the same weight, the effect would be to give the whole earth one mean density, or another, according as the smaller ball of brass or ivory. Now it is true that the experiments give all manner of results from 5:500 to 6:154, but on examining the results, there appears no evidence whatever of the large balls attracting the different small ones more differently. If such were the case, undoubtedly the mean density, determined from different substances would be different; but though such is the case in the preceding list,

and even though it would seem that the lighter balls give the larger densities, yet there is every reason to suppose that the effect is to be attributed to the alteration of the pendulum. Thus it will be seen that the difference is not so much between the results of 2-inch ivory and lead balls suspended in the same way by a single copper-wire, as there is between the results of 2-inch lead balls suspended by bifilar wire, and those of 2-inch ivory, and also that ivory balls differently suspended give results which have differences as great as any. The mode of suspension and the effect of merely increasing the weight of the smaller balls, appears much to exceed that of applying different substances; but not so strong to any law. In fact, the differences are altogether of that character to which the term discordance is applied; following no settled rule, and exhibiting every appearance of as often affecting the truth by a positive as by a negative error. The first three sets, in which a brass rod alone is used, were rather a defiance to the apparatus to fail it could, than seriously intended to help the result. Almost all the experiments were made with a light wooden torsion-rod, and comparatively heavy balls appended. The trying a brass rod itself excepted at the attempt at obtaining a mean density by noting the attraction of the larger balls upon the torsion-rod only, was the introduction of an extreme case, to increase confidence in the more ordinary experiments.

The mean of the whole is 5-677-7, and, rejecting the experiments of which the character would be a priori most doubtful (though it is not certain they ought to be rejected) it is reduced to 5-660-4. From the experiments, by the usual rules of the theory of probabilities (see the notes above), it is an evident truth that the error of this result is within 0-4. Cavendish's result was 5-48.

Besides the confirmation of some of the most material points of the theory of gravitation which results from this experiment, it furnishes a confirmation of the assumption that the earth is solid to the centre, and not, as many have supposed in every age, a hollow shell. The mean density \( \rho \) is very much greater than that of the substances which abound at the surface. All common rocks are under 3, and nothing under 2 of the hardness of 7.27. The earth is as massive as if it were all composed of silver-ore, from the centre to the circumference, so that there must be an increase of density towards the centre. If those who think the earth to be a shell were to presume that its solidity would begin at the utmost surface, they would then be compelled to give to the terrestrial matter, one part with another, a density greater than that of mercury, in order that the whole shell, the hollow part included, might have the mean density which is found for the experiment.

**WEIGHT OF OBSERVATIONS.** This term was first applied in the manner stated in the article Mean. An observer decided the relative merits of his observations by his unassisted recollection of the impression that the various observations made upon his mind at the time of the experiment afforded to him, that is, supposing \( A_1, A_2, \ldots \) to be the result of observation, he attached numbers \( c_1, c_2, \ldots \) proportional to their presumed goodness, and used \( \sum c_i A_i / \sum c_i \) instead of \( \overline{A} = \overline{n} \), for the average. Instead of \( c_1, c_2, \ldots \) any numbers, and in applying the higher branches of the theory of probabilities, it was found that a certain mode of obtaining \( c_1, c_2, \ldots \), while it gave the same mode of using these numbers in the formation of an average, made the result not so important when used, as the arithmetic mean. We here give a sketch of the results of this method in its simplest parts.

1. When a number of discordant observations, made under circumstances in which positive and negative errors are equally likely, do not differ much from the truth, it is exceedingly unlikely that the truth can differ much from the observations, it may be presumed that the chances of the error of any one of those observations lying between \( x \) and \( x + dx \), and between \( a \) and \( a + \delta a \), are severally of the form

\[
\sqrt{\frac{c}{\pi}} e^{-c x^2} \, dx \quad \text{and} \quad \sqrt{\frac{c}{\pi}} e^{-c (a + \delta a)^2} \, dx,
\]

where \( c \) is a constant dependent on the goodness of the observations, and \( a = 3-14159, \ldots \), \( c = 2-718 \).\ldots

* This article is only for the reference of the experiments. Mean will be found much as if \( x = a \).
Even if this law of error do not exist, it is found that the treatment of a considerable number of observations, whatever be the law, is reducible to the same form as those derived from this law, which is now universally assumed by those observers who apply the theory of probabilities to their results.

2. The constant \( c \) is called the weight of the observation, and depends upon the various circumstances which determine their goodness or badness. The greater it is, the better is the class of observations to which it applies. It is approximately found, for a given class of observations, as follows:—Subtract each of the observations from their mean \( \bar{x} \), and then add the square of these differences the square of \( \bar{x} ; \), and then add the square of these differences, and divide it by \( n \) times the square of the mean; and before doing this any convenient quantity may be subtracted from all the observations, provided it is also struck off from the mean.

3. The probable error is that which, taken positively and negatively, there is an even chance an observation shall lie. Thus if there be an even chance (A being the true result) for the result of an observation lying between \( A - a \) and \( A + a \), then \( a \) is the probable error of an observation. To find the probable error, divide \( 4\sigma\frac{\bar{x}}{n} \) by the square root of the weight.

4. The average of the observations is the sum of the weights of the component observations. If \( n \) observations, \( A, A', \ldots \), be made, all of the same weight \( c \), the average is \( \frac{A + A' + \ldots}{n} \), and the probable error is \( \frac{c}{\sqrt{n}} \). But if the weights be \( c_1, c_2, \ldots \), the average is \( \frac{A c_1 + A' c_2 + \ldots}{\sum c_i} \), and the probable error \( \frac{c}{\sqrt{\sum c_i}} \). A concrete example of this is the case of length, surface, capacity, and weight. The angle is another magnitude which has a natural measure [Stand. p. 435]; and, as this has never been out of the hands of geometers, a greater uniformity has prevailed in the measurement of angles than of any other whatsoever. The measures of length obviously regulate those of surface and capacity. There is no other way of defining an area or a solidity, except by describing, for the area, lengths, and for the solidity, surfaces, by which each may be bounded. The number of measures of weight may be obtained by defining, as standards, given bulks of given substances; and as water is the most common and most easily purified of all substances, it has been chosen by common consent as the referee for such standards. A measure of length then is all that is wanted in the first instance, and most nations, antient and modern, have been in the habit of referring all the resulting measures to those of length alone. Nevertheless, there is no small difficulty in obtaining a comparison of a measure of weight obtained from length, and that of that length, by such a manner as to perpetuate the former, if the utmost accuracy be required. (Kater, Construction and Adjustment, &c., 'Phil. Trans.', 1826.) So that the Commissioners recently appointed to revise the standards [Hansard, p. 493] advise that the standard of weight shall no longer be deduced from that of length, but shall be simply a piece of metal or other durable substance.

It is not our object in this article to consider weights and measures in a scientific point of view, nor to give some historical account of the measures actually in use, and some tables of the principal ones, antient and modern. There is no subject whose history is more distinctly divided into three periods, antient, middle, and modern, than this; the weight and measures before the modern period, ending with the decline of the Roman empire, during which the classical standards were preserved and employed; the middle period, during which, while the names and relations of the classical measures were preserved, they were less or more altered, the various differences of national measures began to exist among the people; the modern period, which hardly begins before the seventeenth century, in which the discrepancies between the national measures were so near the same that the writing of the names, &c., are in all languages derived from the same source; nor, in the popular view of measurement, do
they materially differ in length. It is also unquestionable
that in former times, when authentic measures were not so
easily to be obtained, the hands, arms, and feet were much
more frequently used than they are at present, when every
workman, however humble, in possession of a workstation.

George Agricola, presently named, says that in his time
the beginning of the sixteenth century, the French work-
men commonly measured a foot by joining the extremities
of the thumbs, clenched the fingers, and keeping the
heels as widely extended as the thumb. They also used
measuring rods and scales of pitch in public contracts of
portraits politiciis alinrutosque observati; nor is this a
bad measure of a French foot. At what period the
slightly variable measures derived from the living man
were made, I am not able to tell. This care and the other
conventional value, whether among the Greeks or Romans,
unknown. All that can be said is, that none of the earlier
writers enter otherwise than incidentally upon the question.
The fixed and legal measures were of early date. Few
authors give some information upon the subject, even
the poets are frequently cited for their allusions
fixing the end of the ancient period about the middle
of the sixth century. Simply because the charts of writers
who mention the measuring system and measures, for

let it be observed as well known as Homer or Vergi-

lus or Scipio, Priam or Vespasian, there is direct
information on the subject in the works of fragments of
Cicero, Columella, Dioscorides, Heron, Lucan, Pliny,
Ovadius, Pollio, Festus, Plutarchus, Priscus, Priscus,
Pausanias. In his Report of the twenty years ago, he
states expressively on the subject. Priscus of Romano
Flux, who wrote a poem on the subject, was an argument
in Scipio. The archaic Greek, Festus, Plutarchus,
Pausanias.

It may be convenient to end the middle period and
consider the modern with the work of Lucius Persius
573, as being the earliest of the writers who are fre-
cently cited, for success in their attempt to reconcile
the laws of measure and the final results of the
earlier period may be studied and that which precedes

of the invention of printing. All this was more
true in the former part of the time. We may here refer
as exactly, the probability弹簧的 introduction of
measure and weight as a commodity, though retaining
the same names. Nevertheless, the words as we have seen in
Mis. Seventeenth, denotes a mixture of expression, an
intemperate mixture of meaning and between a measure of
the word, measures, as they are called. When the German
rule was introduced, there is not about four Roman miles, the

that a certain number of centuries before, we shall

the Roman system was taken for granted. As the

speaking of a foot or a mile, a measure of

Polybius, Pliny, and others, and the measure of

should be of a different system. It appears,

alike measures; though upon the modern

authors, in fact, may be admitted that the modern

measures are in six words, with the

which had been made to the Lucan

Agricola, whose work, De Ponderibus et Mensuris,

much in use, and several times repeated (Paris, 1533;

Venice, 1532; Basle, 1566), and perhaps others, and

almost seem to hint, in addition to what we have already

cited, that the actual measures of his day, being among

taken from the body: the measures of length, he says, are

members' human corpora, puncti, arenotches, and

the body, the cubit, &c., were only originally derived

the human body; for such an explanation would render

us to say that the armeton and the funicles were names

of measures, which was certain and not so, the

words etymologically, it is both a pole and the measure

described from that pole: had it not been from the double

meaning of that word, we should have been quite positive

of what we now think by far the most probable, namely

that the arms and the feet, reckoned from the

of the body, proper of each and every one.

This work of Agricola, though intended to be on the

and measures of the animal, and really nearly one part

from the Greek and Roman measures. We have

with the name, or the measure of the parts of the body,

cases of extremes and strings. This

of Peter Arabi, although intended to be on the

and measures of the animal, and nearly one part

from the Greek and Roman measures. We have

with the name, or the measure of the parts of the body,

cases of extremes and strings. This

of Peter Arabi, although intended to be on the

and measures of the animal, and nearly one part

from the Greek and Roman measures. We have

with the name, or the measure of the parts of the body,

cases of extremes and strings. This

of Peter Arabi, although intended to be on the

and measures of the animal, and nearly one part

from the Greek and Roman measures. We have

with the name, or the measure of the parts of the body,

cases of extremes and strings. This

of Peter Arabi, although intended to be on the
paper. The surest case in which we can accurately ascertain what proportion this shrinking has taken place is in the plate of Bernard's work on English weights and measures, which a line which is described as 7 English inches has shrunk to 6 inches and 25-thirtieths, or in the proportion of 42 to 41. Other instances give smaller amounts of shrinking: we adopt this ratio of 42 to 41, and that is the reason why the larger the proportion we name, more is our final conclusion weakened: this final conclusion being, that the geometries of the sixteenth century used as much shorter foot than the Roman.

That the mathematicians just named did use a set of measures, forming themselves, in order to avoid the varieties of popular measures, is established by the express assertion of Clavius, who died in 1612, aged 75, and is therefore a contemporary authority. He says, in his commentary on Sacrobosco, 'Emmemandse sunt measurse quibus inquinis iurisprudentiae omnes nationes habeuntur. Centuri certo, tertiariae, quartarum, sextarum, octonarium, ne confusioni oritur ob diversitatem mensurarum in variis regionibus (qualibet namque regio proprias habet propomodum measuras) utilit consequent quam mensuras, quae certe ac ratam apud omnes nationes habeuntur. Centuri, tertiarum, quartarum, sextarum, octonarium, mensuras, of the great diversity of measures. This paper-foot is now within a sixtieth of an inch of nine inches and two-thirds (English), which, increased in the proportion of 41 to 42, is nine inches and nine-tenths. In the second work, he says that his five of his own pages, or of those of ordinary men, make six geometrical pages. Now the pace of an ordinary man, or two steps, is almost exactly five English feet; but we have found that there were other measures, the foot, as 129. English inches, and have therefore considered him as having (by accident, they suppose) measured his degree with very great correctness, whereas, in fact, he is 10 miles wrong. Budæus (followed by Glareanus and others) before the year 1526, in his treatise of Asse, the earliest work on Roman measures, &c., declared that the Roman foot was the same as the Parisian; and Picard, &c., seem to have taken it for granted that Fernel followed Budæus, they might have learnt from Lucas Passus they had been in Budæus, London, 1526, by Basset, nothing in common with the Roman foot.' The treatise of Stöffer, 'De Menestrationibus,' Oppenheim, 1524, contains his configuration of the digit, palm, and foot, separately, the foot being also divided into palms. These agree exceedingly well with the above, and the foot is precisely 9 inches and three-quarters (English). This increased in the ratio of 41 to 42 gives 9.99 inches. The author speaks of the digit, &c., as being the celebrated measures which are used by all or most, and gives no hint whatever of his having made a measure for himself. It may here be noted that the English writers of the period make little mention of this book-system, and, when they do mention it, sometimes confound it with the common and popular system. The most recent, in his 'English Grammar,' according to Stöffer, is two inches and a half less than ours; alluding, no doubt, to the foot we have just cited.

* * *

* We have taken the one which is against ours: in the 'Pathway to Knowledge,' (1996) not the work of Recorder under that name, but a translation of an earlier work, there is no account given in bibliography of six English inches, figured in the translator's preface, but shrunk only by one inch. With reference to this path, we may observe that Jove's, whose sample and laborious account of weights and measures (in his 'Aoytorygkolia, or Aristarchean Survey of Weights and Measures,' London, 1674) makes him a very respectable writer, considers it as a first-rate authority.

* * *

There is little reliance to be placed on the barley standard; nevertheless, this addition to the Roman system of measures has been made by some who had true taste. We can hardly suppose that writers in all cases care fully state that four grains of barley placed side by side give their first and lowest measure, unless they were at least repeating a well-established tradition, founded upon the accustomed practice of preceding ages. Hence the barley, in 64 grains, placed side by side, ought to give their foot: we believe it will be found very difficult to make any barley of our day give more than 10 inches. On trying the first grains we obtained, we found that, by picking out the largest size, we could make 9 inches and a half, or 10 less, the mean size of six inches; but that, taking the grains as they came, 38 gave only five inches. Not wishing however to trust to one trial, we procured the largest specimens of barley which could be got from two different and distant parts of England, and from three different species, and we have placed the three grains. In a first sample, 31 grains placed side by side gave five inches; in a second, 33 grains gave five inches and one-tenth; in a third, 33 grains gave also 5 inches and one-tenth. And yet these grains had differed a little in length from English barley, and we found that the length of the grains differed materially, their breadth very little. So that the antient English standard, which depended, or was said to have depended, upon the length of barley, could have been nothing, this end, was not founded upon so sure a method as that above described, which depended upon the breadths. The foot of 64 barley corns derived from the average of the preceding (rejecting that from the smaller grains of the London sample) is 9.69 inches. The diminution of sounder notions, we see, might be supposed from the other methods of judging, which, however, it must be remembered, have been pushed to their utmost.

We feel persuaded from all that proceeds, not only that at the beginning of the sixteenth century there was no distinction made between the measures of the learned and the Roman measures, but that the Roman foot, the foundation of all, was taken to be considerably shorter than the truth, having been probably recovered from the human body. A record of standards of sounder notions, we see, traces of the same sort of thing. For instance, in the second edition of the mathematical Lexicon of Vitalia (1690), the first edition (1668) being silent on the matter, an article on measures is introduced in which the only authorities adduced are the 1st Edition of Albertus ab Alexandre, in which there is nothing but description of antient measures, and the work of George Agricola already cited. The Roman foot was recovered with tolerable ease as soon as it was looked for. Leonard di Portis, an Italian lawyer and Lucas Passus, another lawyer, wrote elaborately on the antient weights and measures in 1573. Those who would see more of this subject in the sixteenth century must peruse, for the writings of Alciatus, Aesop, Geofredo, Budaschar, Budaschar, Montesius, Martens, Lebrixia (Nabresienne), Neandt, Pas, Passus, Portius, Villaplavina, &c.

As soon as the middle period is past, the history of weights and measures shows our own time ceases to be European, and, with the exception of those of England and France, we need not, in so short a sketch as the present, give any very close account of the various national measures.

In England, it seems as if the standards were tolerably well settled and widely diffused at so early a period that the writers of this country took comparatively little notice of the system which the continental mathematicians used for their own communications. That the ear of barley and the barleycorn is still the family measure, it is difficult to suppose that the foot, even this. 

* We do not believe the story of Henry I. ordering that the yard should be of the length of his arm.

* A silver penny.
a bol. &c. And the interpretation of the older scientific writers on measures is agreeable to the common meaning of the word. It is first grounded,' says Oughtred, 'and principle of our English measuring from Bayly comes.' But it is so difficult to know how much of the sharp end of a barley-corn must be cut or worn away before it becomes what was called 'round,' that this mode of measuring barley-corns is very indefinite.

Standards were made at early periods for various statutes; one of the earliest is one of Edward I. of uncertain date, which directs that a standard of bushels, gallons, and eils, shall be kept in every town, agreeing with the king's measure. By the measure of law of this country has been fortunate, and its standards have, for commercial purposes, fully deserved the name. But the measure of capacity [GALLON] remained various in spite of all acts of Parliament. In the year 1680 there was a dispute in the House of Commons about the measure of the gallon. From general opinion, which gave 231 cubic inches, and with which, in fact, the gallons in common use agreed, as was proved by the movements of Oughtred, Gunter, Briggs, and others. The customary standard at the Guildhall, which, though not a legal standard, was considered as such, even by the law-officers of the crown, and which, though in reality only 224 cubic inches, was always taken to be 231 inches: The real legal standard, preserved at the Treasury, containing 228 cubic inches. (One cubic inch = 1.6387 cubic centimeters.) 'A gallon is,' that because of the frothing of the ale or beer, the quantity becomes less, and therefore such liquors as did not so yield froth, as wine, oyle, and the like, should be considered in determining the measure. The Report of one of the Committees states that the wine as it was sold had shrunk in capacity, until it was arrested at 231 cubic inches by a fiscal definition. That this value was laid down by the statute of 5 Anne, cap. 27, is certain; and the origin of this definition is that it was inserted into a statute having nothing to do with weights and measures, and has been as follows—A little after 1700, an information was tried in the Exchequer against one Barker, for having imported more of Alicante wine than he had paid duty for. 0. In the words of the statute, which is inserted into a statute having nothing to do with weights and measures, the measure of the gallon at Guildhall (said to contain 231 cubic inches) was the standard. But the defendants appealed to the law, which required that a standard gallon should be kept at the Treasury, proved that there was such a gallon at the Treasury containing 228 cubic inches, and established, by the evidence of the oldest persons in the trade, that the pipes and hogsheads which came from Spain had always contained the proper number of the real standard gallons. A jury was withdrawn, and the law-officers of the crown took their stand on the explanation of the statute, and the jury decided in favor of the defendants. Another instance of confusion could hardly be imagined: the legal gallon had gradually diminished more than 50 cubic inches; the merchants in one particular trade continued to import and to pay duty by the real gallon, and were branded as those who, in common with the rest of the world, had forgotten what the real gallon was, and sued for penalties upon appeal to what was no more a legal standard than the measure in a private shop.

There is something curious about the history of the experiment [GALLON] mentioned by Ward, who was an eyewitness, and wrote just after the statute of Anne, when his account could do no harm. The gallon was found to be 228 cubic inches. But this was not the only gallon, for the gallon at Guildhall, (said to contain 231 cubic inches) was the standard. But the defendants appealed to the law, which required that a standard gallon should be kept at the Treasury, proved that there was such a gallon at the Treasury containing 228 cubic inches, and established, by the evidence of the oldest persons in the trade, that the pipes and hogsheads which came from Spain had always contained the proper number of the real standard gallons. A jury was withdrawn, and the law-officers of the crown took their stand on the explanation of the statute, and the jury decided in favor of the defendants. Another instance of confusion could hardly be imagined: the legal gallon had gradually diminished more than 50 cubic inches; the merchants in one particular trade continued to import and to pay duty by the real gallon, and were branded as those who, in common with the rest of the world, had forgotten what the real gallon was, and sued for penalties upon appeal to what was no more a legal standard than the measure in a private shop.

We believe, in acting to declare that the old gallon which almost all the statutes refer to, is none other than what will be the volume of a large lyer's measure, just as Oughtred, the old division of the gallon into that of wine measure, ale and beer measure, and dry measure, was not unknown to the law, but even to writing on arithmetic, till the beginning of the seventeenth century. And when Briggs, Oughtred, &c. measured the gallons, did they divide them into more than two kinds—for ale and wine. Oughtred, who measured beer, and found 273 1/4 cubic inches for the deduced gallon, imagines this to be the ale gallon. It was undoubtedly the old Winchester gallon, before its content was a little reduced. The statute of 1798, and all that followed, continued in use in Ireland up to the introduction of the decimal system; and even in England, as late as 1727, Arbuthnot takes it for the existing dry measure. Perhaps we have the first time in which, and the first person by whom, the distinction of the measure of ale and wine was made known, and the gallon to contain 273 1/4 cubic inches, with the good citation from Wybred ('Tactometria,' 1650, p. 266):—'Now as to Mr. Oughtred's ale gallon of 272 1/4 inches, the said Mr. Reynolds (John Reynolds, a clerk in the Mint, often referred to by Wybred as a mathematician and experimenter) indeed allows both of such a Gallon measure, but not for any liquid thing, but for dry things, as Corne, Coals, Salt, and other dry things measurable by this kind of Measure, and so calleth it the drie Gallon measure: and thereupon he will have to be 3 severall Gallons (or other Measures, of which the first for dry Waters, and the like, another for Ale and Beer, and a third for Corne, Coales, and the like.' Wybred, rejecting the distinction of the dry and ale gallons, made his wine or ale gallons to be 228 and 230 cubic inches, by a series of carefully considered experiments, and the only good experimenter, with access to existing standards, and as good an experimenter to suggest something like the actual truth, should not have been able to find out the mere existence of the large or small gallon, as it was an extreme confusion in which the subject was then enveloped.

There has been in various quarters a disposition to suppose that the varieties of gallons arose from the varieties of pounds, since the original definition of the gallon depended on the pound. We think that this is a mistake, and we do not imagine that it was done for set purpose, but by confounding one species of pound with the other, in the way of common mistake. There is among most antiquarians a perverse unwillingness to admit human frailty among those phenomena of the human mind which has caused many an hour to be thrown away in trying to reconcile the Greek musical scales [Tetrachords], and many more in trying to find out the rude forefathers of all kinds of nations an accurate and self-consistent system of weights and measures. Thus we find that even the English, after having legislated, legislating for educated men, after declining in one paragraph that none but troy weight is to be used, has introduced avoirdupois weight in the very next paragraph,—we never permit ourselves to suppose that such a thing could have taken place in the reign of James VI. or Elizabeth. Now it certainly does happen that there is a close relation not only between the old gallons and the weights, but even between the different varieties of the old gallons and the weights. There was a gallon of 226 cubic inches, in the Exchequer as a standard; there was one of 272 1/4 inches, in common use; there was one of 231 inches, in common use; and there was one of 224 inches, in the Guildhall. Now 283 and 232 are, as near as integers will allow it, in the proportion of about 1.2 to 1 to the pound troy, and 272 and 224 are as nearly in the same proportion. It is unlikely that this should be accidental.

Common usage, in the sixteenth century, made more distinctions of measure than have lasted. The editor of the 'Pathway to Knowledge' gives four sorts of pounds in use: the Tower pound (already mentioned in Troy), the London pound (of 2400 pounds=2240 pounds), the Winchester pound (of 2520 pounds), and the Oxford pound (of 2680 pounds). The Oxford pound is also called the old measure, as that of air, and contains eight pounds of wine: it is also made the ounce gallon containing eight pounds of water. We allude to the College of Physicians, in the matter of the old apothecaries' measure, presently mentioned. The mistake was exceedingly natural, almost inevitable, but it shows what extreme care is necessary.
the troy and ‘haberdapys,’ the substill, and the foyle. The word substill was not the one mentioned in Tare, at least not as such, so let the reader try to understand it himself:—The pound substill was used for that in small quantities it may be made rattle to represent any other weight whatsoever, as fourpenny weight troy, or less to answer in due proportion under the law. The pound substill was convenient to use, with his pac, every part sensible and severally to be bandied. This weight is unsuitable, to assaye Maisters and such as can make triall of minerals, and not knowne to many other, neither is there any use thereof, in ordinarie accomplis. This seems to me the most practical piece, an assayer would hang it up for trial, was made to represent a pound, and the fineness expressed in ounces of that small pound would of course represent that of the actual pound. The pound foyle was less than the pound troy by its fifth part, and was used for gold foil and for Base. In the two former cases it obviously means that the workman paid himself for labour and loss by selling four-fifths of a pound of wire or foil at the price of a pound of bullion. And many varieties of measure arise in this way, namely, by owing, not the actual weight, but the amount of a given name at a given price. A wholesale bookseller now says that he sells 20 or 24, meaning that he who buys two dozen shall have one more; but in the sixteenth century this usage existed, it would have been put down that two dozen of books are twenty-five.

It is needless to give an account of the old standards of weight mentioned by the committee of 1758, as many of them are lost; a much greater agreement was found to exist with the preceding made as various times than was observed in regard to the standards of capacity. The origin and history of the different weights is alluded to in Averdupois and Troy; of the standards of length in Standard, in which last article will be found an account of the transition to the newly established rectified measures. That period is probably distant when the English public shall enjoy the advantages of a uniform decimal system of weights and measures—the only one which is sure of stability. An opinion is gaining ground that the best method of ultimate and fundamental is by being legally exact and by being there, and this is recommended by the commissioners who have recently reported. [Standard.] Nothing, as it fortunately happens, can be easier than this change; the introduction of coins of two shilling each, in place of threepence, followed by that of coins of two shilling and penny each, might be made without requiring any alteration in the habits or calculations of any one. It is the advantage of this proposition that the two new coins which it requires to be coined form parts of the one thousand, and that the subsequent alteration of the copper is made. As soon as these coins are well established, an alteration of four per cent. in the copper coinage, or the enactment that two and half shilling shall pass for the silver shilling, is the whole system of plate, and the precious metal, need alter its weight; but the twopence-halfpenny coins of their proper name, the two-shilling coin of ten teepose-halfpenny coins (also under their proper name), and the twopence-halfpenny of ten farthings as at present. As soon as this change is made, and the convenience of its arithmetic found by experience, it will not be long before there is a demand for the extension of the principle to weights and measures. And it would be well if those who endeavour to bring about a reform in such a matter, would make use of the encouragement of the only change which a government can immediately command—that for one calculation which is made upon goods, hundreds are made upon money—and that, if the small alteration which is required to make with troy weight, is not merely pure duty, it is, there is little chance of the more extensive changes which the weights and measures will require.

We now describe the English weights and measures as they stood on the last day of the year 1825, immediately before the introduction by law of the imperial measure, with some remarks on their states at different times. As it is not to such an article as the present that the young arithmetician will refer, it will not be necessary to give more than a condensed set of tables. For the modern compiler who has to acknowledge great assistance from Dr. Kelly's 'Cambist,' the standard work on the subject.

**Troy Weight.** This weight is said to have always been

the standard weight of the country: on this assertion we have some doubts; but this is not the place to enter on them at length. For the troy pound is 20 ounces; the troy penny is 24 grains. The troy pound is 5760 grains. There is but one grain in use, whether troy or averdupois, and a cubic inch of pure water is 232.458 grains (barometer 30 inches, thermometer 62° Fæ). A pound of water is 720.48 grains. Wheat and bread were once measured by this weight, but latterly only gold and silver. It is usual to say that precious stones are also measured by troy weight; but, as may be supposed, the measure of these is the grain. The diamond is measured by grains of dupois, to the troy ounce; so that the carat is 34 grains, very nearly. In pearls, the old troy measure already noticing still exists; for the pearl grain is one-fifth less than the troy grain. In the seventeenth century the goldsmiths divided the ounce troy into 12 carats of four grains each; this practitioner counted the pound troy contained 1152 gold-carat grains. They also divided the ounce into 150 carats of four grains each, for diamonds: the pound troy contained 7200 diamond-carat grains. But now the carat has only the sense noted under that word, for gold and silver; and is altered as above for diamonds.

According to the old statutes, the pound troy is 7980 grains; for 32 grains are to make a pennyweight, 20 pennyweights a troy ounce, and 12 troy ounces a troy pound. This, or why the pennyweight was first made 24 grains. In some old books a grain is 20 mites, a mite 24 drouetes, a drouete 20 pereotes, and a pereote 24 blanks. This division of the grain into 230,400 parts must of course have been for accounting: it is said to have been confined to the moneyers.

**Apothecaries' Weight.** In dispensing medicines, the pound troy (Does that weight ever occur in prescriptions?) is divided into 12 ounces, the ounce into 8 drams, the dram into 3 fluidounces, and the fluidounce into 8 drams. In the following, it is to be weighed by what we now call apothecaries' weight. The fact seems to be that in the first instance the more precious drugs, as musk, were weighed by troy weight, in the same manner as the more precious metals; and that the common medicines were dispensed by fractions of what was the common pound, as we shall see under the next head.

**Apothecaries' fluid measure.** In 1836, in the new edition of the Code of 1828, the Colline of France, Dr. Young (who has reduced them from Vega), the apothecaries' grains used in different countries are as follows:—1000 English grains make 1125 Austrian, 956 Besirne, 981 French, 830 Genoese, 958 German, 975 Italian, 896 Neapolitan, 993 Spanish, 954 Portuguese, 982 Roman, 893 Spanish, 988 Venetian.

**Averdupois weight.** The pound is 16 ounces, and the ounce 16 drams: the modern pound is 7000 grains (the ounce, 437.5 grains); the troy pound and ounce are 20 and 27 grains and 11-32nds of a grain. The hundredweight is 100 pounds, and the ton 20 hundredweight. The cubic foot

* Cocker, Wighste, re., say that a pennyweight is 22/23 oz. and 24/25 oz. of silver is. 150.
* A grain of wheat was more nearly a pound, and some of our readers will remember the old saying.—

"A pottle's pence.
All the world round."

The second line of this was certainly not true, and the first only approximately. It is a good example of the imperial system the weight, which is literally true, may be substituted.

A pint of pure water.

Weighs a pound and a quarter.

* It is not noted in the 'Pharmacopoea' that the fluid ounce, when it is an ounce avoirdupois; a preceding sentence in that work implies that medical men are never to use anything but troy weight.
of water is $62,321,006$ pounds avoirdupois. The stone is the 8th part of the hundredweight, or 14 pounds. The ton of shipping is not a weight but a measure, 42 cubic feet, hollow. At the beginning of the 17th century, heraldic terms which are made of baber/avv/avv, the word is not applied to weight, but to goods weighed. A charter of Edward I. speaks, 'de aversis pond., et de alia rebis subtilibus'; and no mention is made of avoirdupois weight. In the 17th century, Gerard Malynes, whose *Lex Mercatoria* was published in 1686, says that it serves to weigh 'all kind of grocery ware, as also butter, cheese, flesh, tallow, wax, and every other thing.' The name of *garbe*, and whereof Issach th refuse or waste.

The old merchants' pound, which was 15 ounces [Troy], may have been the origin of the modern avoirdupois pound. Fleta says everything was weighed by it except gold, silver, and drugs; but it is to be remembered that this does not mean that gold and silver were weighed by Troy weight; for it is well known that until a change was made by Henry VIII. in 1527, gold and silver were weighed by the Tower pound of 14 ounces. The modern avoirdupois pound is 14 ounces, 12 pennyweights, all but 8 grains Troy. The standards of Elizabeth agree tolerably well with this; but it is to be noticed that unless we suppose two avoirdupois pounds, one ancient, and one modern, and the latter is doubt whether the modern pound was uniform. Dr. Kelly says, 'The old commercial weight of England, which is still retained in Scotland, is about one-twelfth heavier than avoirdupois, the pound being 7890 grains troy.' This has been long the weight of a Troy ounce, 'but in Scotland a pound of 4.89 grains is now deposited. Our suspicion is this, that the old commercial pound, probably differing in different places, though supposed to be uniform, gradually gained the name of avoirdupois; and that the standards deposited in the Exchequer in the time of Elizabeth, which certainly did not agree with the arithmetical writers of the same date, were probably derived either from this old merchants' pound of 15 ounces Troy, or from a selection out of the varying specimens of a pound derived from it. In the *Pathway* the 'pound baberdupois' is 16 ounces Troy. In the legal dictionaries, every dragee 3 scruples, every scruple 20 grains; giving 7890 grains to the pound. This is the probable origin of the old pound which Dr. Kelly mentions, and it happens to contain precisely the same number of grains as the old statute 2 pounds before 32 grains took the place of 24 in the pennyweight. And this shows the origin of apothecaries' weight: medicines were dispensed by this old subdivision of the pound, and continued to be so, though the square inch had supplanted the old one. It was then natural that this ounce, drachm, and scruple, which were no aliquot parts of the new avoirdupois pound, but which were aliquot parts of the pound troy, should be referred by arithmetical writers to the old standards. We may, therefore, consider the yeor-general of the Ordinance, and hardly could have failed to be correctly informed, gives the same pound and subdivisions. Moore's *Arithmetic* was first published in 1693. Jeake, as late as 1674, gives the same division and the same pound of 7890 grains; and Harris, as late as 1724, does the same in the third edition of the *Lexicon Technicum.* Jeake gives several citations tending to show that there was no universal agreement about the pound avoirdupois, and the laws and ordinances of the time, he says, agree in making 56 lb. avoirdupois equal to 67 lb. troy (or 6942 grains to the pound), but both afterwars put 68 for 671 (which gives 6994 grains). Others, he continues, affirm the pound avoirdupois to be 14 ounces troy, and others 16 ounces. In the old writers, the older writers hardly mention avoirdupois weight: Recorde not at all, and Melliis slightly, not subdividing the ounce. Hartwell, an editor of Recorde (1648), mentions this pound and 7890 grains, divided as above, and says it

*In this case many different stone weights; one every but that of 14 pounds is now illegal.*

Abolished in 1815.

In modern times, others may lead to the suspicion that the pound of which we now speak (being that which was called avoirdupois in the sixteenth century) was not the same as that which was called *paravoit* in the *Glosseorum Deponens,* a pamphlet, asserting that the common avoirdupois was the ancient pound, and the new pound a *pound paravoit.*

The writer of books might invoke a pound for this measure, because medicines are not dispensed by pounds, but as they might cost billions, trillions, &c., named, those names being never used. But the druggists continued to buy and sell wholesale by avoirdupois weight.

P. C., No. 1705.

is used by apothecaries. Oughtred, mentioning Houghtal's pound of 6912 grains, compares it only with the English Troy pound, without mention of any other. All this shows that Oughtred was not deceived, that the old writers had a complete want of agreement as to what constituted avoirdupois weight, which continued in some degree till the end. Nevertheless in the middle of the century, Wyberd, who measured for himself, and his friend Recorde, a pound that was evidently the same as the Troy pound, to the 17 as 14 (which gives 69944 grains, agreeing with Walton and Malynes, though they say that the then common notion was that the ratio was 73 to 60 (which gives 7896 grains). They say this was a very nice experiment, but we cannot find the place, gives the ratio 175 to 144, or 6890 grains. Down to the 16th century, the avoirdupois pound varied a little, according to the notion of the writer: Dilworth makes it 69949 grains; Dr. Robert Smith, 7000 grains; Bonnycastle, 69995 grains. And even since that time it has been on the increase, and furthering to a pound avoirdupois, an editor of the last-named writer will not be obliged to the statute, but adds the 123rd part of a grain.

**Long Measure.**—Three barleycorns make an inch, 12 inches a foot, 3 feet a yard, 54 yards a pole or perch, 40 poles a furlong, 8 furlongs (1760) a mile. Also 24 inches are a foot, 3 feet a yard, 100 links, 10 chains make a furlong, and 80 such chains make a mile. The inch is sometimes divided into 12 lines (as in France), but often into tenths or eightths. On our old measures, see *League* and *Mile.* The yard is frequently called an ell in old books; *commonly,* Recorde says, that a yard and a half of one yard was divided into every 16 nails. A goad is an old name for a yard and a half. The hand (antiently hand), used in measuring the height of horses, is fixed at 4 inches by 27 Henry VIII., cap. 6. The furlong is probably a corruption of forty leagues, from its former use as a space of one league. As a large as a furlong, seems to us to carry absurdity on the face of it. The etymologists of measures are not always fortunate; Verstegan derives Troy weight from Troyviant, the mythological name for Leucon; and Jeake will have avoirdupois to be oversize, because the pound is greater than in Troy weight.

**Square Measure.**—A square perch is 303 square yards; 40 square perches are a rood (formerly also farthedeon), 40 roods make an acre, and 100 acres make a square mile. A square mile is also termed 1600 square perches, or 4840 square yards. Four square perches were antiently called a day's work. The rod is the same word as rod: Melliis says they rode make an acre. The old terms which have come down from *Domesday Book* at latest, the hide, pound, yard, perch, yard, are wholly unsettled as to what magnitudes they meant.

The cubic measure, or measures of capacity, do not immediately depend upon the cubic foot, except in the case of timber. Forty cubic feet of rough timber, or fifty feet of hewn timber, make a load.

The preceding measures have been untouched by the act which introduced the imperial measures. The old measures of capacity, the wine measure, ale and beer measure, and the dry measure, are now replaced by the imperial measure.

**Old Dry or Corn Measure.**—The gallon is 268-6 cubic inches. Two pints make a quart, two quarts a pottle, two pottles a gallon, two gallons a peck, four pecks a bushel, two bushels a strike, two strikes a hundred, and 8000 a quarter (eight bushels), 5 quarters a way or load, and

*In recent times the word perch has been almost confined to the square perch.*

To that article we may add that our conjecture relative to the computed miles, as distinguished from measured miles, namely, that the former were sometimes computed on maps, is not uncommon. On an old register of the English Grew ('Vuln. Trans.,' 1711). 'And the reason of their mistakes seems to have been reckoning only by the map; that is, by computed and not by measured miles.'

Mr. Davies Gilbert, in his evidence before the Committee on weights and measures, told the House that the experiments were two: first, as to three; observing that the money and the money weight have three denominations—penny, shilling, and pound; secondly, as to Rod or rod merely means a piece of wood much longer than it is broad or thick. So the word road commonly was used for the corn; and when Milton says that Satan, 'as he flould many a rod,' is taking the length of his hero, and not the ground which he covered.
two weys a last. In measuring grain, the bushel is struck, that is, the part which more fills the measure is selected, and so on other goods. In 1562, the pound was abolished.

...
203

The Scottish liquid gallon was 833-6272 English cubic inches. Four gills made a mutchkin, 2 mutchkins a choppin, 2 chopins a pint, and eight pints a gallon. The Scotch foot was made from the extremity of a line drawn at arm's length between the heel and the tip of the middle finger; their measure, however, had been altered in 1796 into the same as that of the English foot. They had only one liquid measure; but they had two dry measures; the first for wheat, peas, beans, &c., the second for barley and oats. In the first the peck contained 533-561 English cubic inches. Four lippies made a peck, and 44 lippies, 1 pint, or 48 lippies, 1 quart, or 384 lippies, 1 English bushel. The second measure was divided in the same way, but the peck was 807-576 English cubic inches.

On the Irish measures, previous to the introduction of the imperial system, there is nothing to remark, except that the bushel and three-quarters was divided into the lime bushel 8, the malt gallon 272 cubic inches, and the liquid gallon 217-5 cubic inches. The pole was 7 yards, which made the mile equal to an English mile and three-elevenths, and the acre greater than the English acre in the proportion of 121 to 100.

We have not space to enter into the ancient history of French measures, for which the reader may consult Plucton's 'Métrie,' Paris, 1780. On the measurement of the earth, on which theprecedeSpace, see T.A.T.A.T. Ervice, p. 216. The system of measures derived from this great operation was introduced in 1795 (by the law of 18 Germinal, An III., or, to speak intelligibly, March, 1795) it being noted that the survey was then completed, but because it proved necessary and expedient to establish a single measure, the committee decided to introduce a new 'mètre provisoire' obtained from the existing surveys. The definitive metrical system was introduced in 1799, but it was found impossible to drive out the old subdivisions; accordingly, in 1812, the system was prolonged to the last subdivisions, and it is now fully established upon the metrical system; in which the measures, &c. were taken from the metrical system, and with the ancient subdivisions adapted to them. Even this was very far from entirely driving out the old system. Until 1795 a law was in force ordaining that from and after the 1st of January, 1740, no other weights nor measures should be used except those of the pure metrical system, and this law seems to have been effective. In the ancient French system the pole was 39.21770 meters, and the acre (that is, in Paris) 46.95 of the same. The toise was six feet. For the triangular measures see Mile. The arpent d'ordonnance was 1 acre, 1 rood, 2 perches (English); the arpent com- man 1 acre 7 perches, the arpent de Paris 3 roods 15 perches English. The acre de Normandie was 2 acres 2 perches. The toise de Normandie was 6.568 English toises. The English measures of liquid, the pint was less than the English quart by its 1/8th part. Two boisons made a demi-terre, 2 demi-terres made a choppin, 2 chopins a pint, 2 pintes a quarte, 4 quartes a setier, 30 setiers a muid (707.95 cubic feet) or 1 English bushel. For the English bushel, 3 boisons made a minot, 2 minots a mine, 2 mines a setier, 12 setiers a muid. The muid was 1-108 English bushels. The principal weight, called poids de marse, was the weight of 9216 French grains, or 7585 English grains; 707.95 cubic feet was the content of an English bushel. 1-108 English bushels, 32 marc a livre. The apothecaries divided the ounce into 2 duelles, the duelle into 4 siliques, and also into 6 sextules and into 8 drachms, the drachm into 3 scruples, and therefore the scruple into 12 grains.

The new system is called metrical, as derived from the measurement of the earth. Its first measure, the metre, is presumed to be the ten-millionth part of a line drawn from the pole to the equator, and is 39-0707 English inches. A Vide, see Miles. A Vide also the Uniformity of Weights and Measures in Scotland, &c., second edition, Edinburgh, 1879.

On the old Winchester gallon, already mentioned. On this work, that of Ronn de L'Ise (1799) and the anonymous 'Métrie universelle.' It is important to remark that while the authorities who have endeavored to prove the pre-existence of the system have been vitiated by the assumption that a very accurate knowledge of the earth's surface existed, from the division of the measure of the sphere into degrees, minutes and seconds, the same or a similar system of weights and measures, even those anterior to Greek and Roman times, were used. Graevus had the lead way by finding English weights and measures from the Egyptian pyramid. All persons who have ventured to cast up the table of the Egyptian weights and measures, and to compare it with those of modern times, will be impressed with the conclusion that the Egyptian system has been continued and perhaps improved. All the Egyptians were accustomed to imagine some grand and mysterious connection between existing measures and the number of the periods which they have been shown to have existed. Dr. Kelly (Camblit, l. 141) makes it 10-543 grains, for which he gives no authority. Dr. Kelly (Camblit, l. 141) makes it 10-543 grains, for which he gives no authority.

2 There is a large list of the fundamental measures of length, which are those most used, in 'Table of Chronological and Square Measures, by W. Woodhouse, (London, West, 1838).

3 We find the weights, &c. in the works from which the list of places was taken, rather different from those in Dr. Kelly's work. But the latter work is the best authority, and nothing but evidence can alter any weight or measure that has been fixed. In what concerns the English weight, it is almost in any second-rate writer to differ from it without stating why.
Colonies. Follow in general the weights and measures of the mother country, except where they have passed under other governments, in which case there is usually a mixture of the two.

Constantinople. The cheque is 4,057 grains. The okz is 2,355 pounds avoirdupois. The kilow (dry) is 7,296 gallons. The almid is 1,150 gallons. The pike is 27 inches. The measures of Turkey are very imperfectly known.

Denmark. The pound for gold and silver is 7,206 grains. The commercial pound is 1,025 pounds avoirdupois. The barrel is 3,626 bushels. The vart is 1,700 gallons. The foot, or half ell, is the Rhineford foot of 12:950 English inches. The toende of corn is 54 acres.

Florence and Leghorn. The cantaro is 150 pounds avoirdupois. The bushel is 902 bushels. The barile is 10-033 gallons. The baccio is 22-98 English inches. The accata is 1 acre 36 perches.

Frankfort. For gold and silver, the Cologne marc. The common pound is 1 lb. avoirdupois. The center is 112-25 lb. avoirdupois. The mallet is 2-375 bushels. The omm is 32-454 gallons. The foot is 11-27 inches, the ell 21-24 inches.

Genoa. The mark is 3,785 grains. The poids fort is 1,214 pounds avoirdupois; the poids faible one sixth less. The last is 3,611 bushels. The 10-9:1098 quarters is 19-1158 inches. The foot is 11-28 inches. The chefelle (quantity usually sown with a chefeff) of land is 1 acre 6 perches.

Hamburg. The Cologne marc is 3,608 grains; the pound troy is two mares. The commercial pound is 1,069 pounds. The last of 3,616 bushels. The 10-9:1092 quarters is 19-1151 inches. The foot is 11-27 inches. The chefeff (quantity usually sown with a chefeff) of land is 1 acre 6 perches.

Holand. The marc is 3,798 grains; the pound is 2 mares. The last of 3,616 bushels. The 10-9:1092 quarters is 19-1151 inches. The foot is 11-27 inches. The chefeff (quantity usually sown with a chefeff) of land is 1 acre 6 perches.

Ionian Islands. The weights and measures are mostly Venetian and Turkish.

Lubeck. For gold and silver, as at Hamburg. The commercial pound is 1,069 lb. avoirdupois. The chefeff is 192 bushels. The alm is 31-85 gallons. The foot or half ell is 11-346 inches.

Malta. The pound for gold and silver is 4,886 grains. The commercial pound is 1,743 pounds avoirdupois. The st calculated for 1,679 bushels. The foot is 11-167 inches. The canna (8 palme) is 81-9 inches.

Milan. The mark is 3,627 grains. The pound sottile is 7,306 pounds avoirdupois; the pound grosso is 1,682 pounds avoirdupois. The mozago (32 quartari) is 4-0234 bushels. The brende (12 quartari) is 13-71 gallons. The baccio is 23-42 inches. The metrical system is also introduced, with Italian names.

Naples. The pound for gold and silver is 4,950 grains. The cantaro grosso is 1,675 pounds avoirdupois. The cantaro piccino is 1,007 pounds avoirdupois. The tomolo is 1,047 bushels. The barile is 9-172 gallons. The palmo is 10-38 inches. The mozago is 3 roods 12 perches.

Netherlands. Since 1820, the French metrical system has been in use.

Portugal. The marc is 3,541-5 grains. The commercial pound is 1,0119 pounds avoirdupois. The moyo is 23-39 bushels. The almad is 3-6407 gallons. The foot is 12-944 inches.

Prussia. (New system, established 1816.) The Cologne marc is 3,600 grains; two marcas are a commercial pound, or 1,0311 pounds avoirdupois. The scheffel is 1,0116 bushels. The eimer is 15-11 gallons. The foot is 12-356 inches, the ell two-thirds of a metre. The mor is 1 acre 2 roods 21 perches.

Rome. The pound is 5,234 grains or 7,774 pounds avoirdupois. The rubbio (4 quarti) is 8-1012 bushels. The barile (32 boccali) is 12-941 gallons. The foot is 11-72 inches. The builders' canna, of 10 palms, is 67-96 inches.

Russia. There is but one pound, 9029 pounds of a pound avoirdupois. The poleb is 36 lb. avoirdupois. The chertwert is 3,709 bushels. The vetro is 2,704 gallons. The inch is 13-1 inches; the English inch is 13 inches; the foot is 13-1 inches; but the English foot is in common use. The desertina is 2 acres, 2 roods, 32 perches.

Saxony. For gold and silver, the Cologne marc. The commercial pound is 1,014 pounds avoirdupois. The Dresdin (24 schilling) is 69-85 bushels; the Leipizig wispel, 91-747 bushels. The Dresden eimer is 14-89 gallons; the Leipizig eimer 16-75 gallons. The Dresden foot is 11-14 inches; the Leipizig foot is 11-13 inches. The acre is 1 acre, 1 rood, 32 perches.

Sicily. The pound is 7 pounds avoirdupois. The cantaro grosso is 192-5 pounds avoirdupois; the cantaro wottile is 175 lb. avoirdupois. The salema grosso is 9-46 bushels; the salma generale 7-39 bushels. The salma of wine is 19-23 litres. The palm is 9-5 inches.

Smyrna. The cheque is 4,058 grains. The rottolo is 1-7295 pounds avoirdupois. The kilow is 11-3 gallons.

Spain. The Castillian marc for gold and silver is 4,800 grains. The commercial pound is 1,014 pounds avoirdupois. The fansage is 1-55 bushels. The arroba of wine is 3-338 gallons. The foot is 11-123 inches; the vara is 33-384 inches. The fanegada (for corn land) is 1 acre, 21 perches.

Sweden. The Mint marc is 3,252 grains. The commercial pound is 9,076 lb. avoirdupois. The dry tunne is 4-028 bushels; the liquid tunna is 48 kanns of 7,576 gallons each. The foot, or half-ell, is 11-694 inches. The tuneland is 2 acre, 1 rood.

United States. The weights and measures are those of England before the late alterations.

Venice. The marc for gold and silver is 3,601-5 grains. The pound peso grosso is 1,0818 lb. avoirdupois. The pound peso tostillo is 664 pounds avoirdupois. The stop 2 bushels. The anfora is 114-1 gallons. The braecco for woollen is 26-61 inches; for silk, 24-8 inches. The foot is 13-68 inches.

We now proceed to the weights and measures of the different nations, taking first the relations of the various denominations to one another, and afterwards the fundamental comparisons of their values with the modern weights and measures.

The Romans had a mode of dividing the as or libra which they transferred upon occasion to any unit. The whole, whether an as or anything else, consisted of twelve unciae, so that the uncia became little more than a name for the twelfth part. The division stood thus—

1 uncia was Sesiuncula, or Sesiuncx.
2 Sextans (a sixth),
3 Quadrans (a fourth), or Teruncia.
4 (a third),
5 Quin uncia.
6 Semis, or Semiss (a half).
7 Sept uncia.
8 Bess, or Bessia.
9 Dodrans.
10 Dextans, or Denticulae.
11 Decuns.

The libra of weight was thus subdivided:—3 siliquae, one obolus; 2 oboli, one scrupulum; 4 scrupliculae, one sex quinaria; 6 sex quinariae; 8 scrupliculae; 8 scrupliculae, one duella; 3 duellae, one uncia; 12 unciae, one uncia. In later times, the uncia was divided into 8 drachmae or 3 scrupula each. This mode of dividing an integer into 288 scrupula runs through other branches of their system, and is also used in modern postal weights in a unit. The obolus in the preceding system rather belongs to a later period in which the Greek divisions were introduced, the ounce being made 8 drachmata of 3 scrupula or 6 oboli each. The uncia appears as ὀβρια in the later Greek writers.

The length of the pes, or foot, was divided not only into 12 unciae, but also into 16 digits. In such Roman foot-rules as have been found, all have the digital division, some both, but none the uncial without the digital. And 4 digits are one palma; 4 palmi, one pes; 16 pedes, one palmine; 16 pedes, one cubitus; 24 pedes, one gradus; 2 gradus, or 5 pedes, one pasma; 2 pasma,
The following measures are identical in pairs, if the *mēter* be two amphorae:—The χερις and the congius; the *eisarix* and the sextarius; the *kēlyx* and the hemina; the *kryptos* and the quartarius; the *pēllēn* and the acuta.

All the Greek measures above given are Attic: there are some variations of description which, if not erroneous, probably belong to other parts of Greece. It is customary to divide the Greek measures into two collections, without any attempt to distinguish at what times, at which places, and by whom they were in use; so that Homer and Athenaeus, or Herodotus and Galen, may appear as authorities in the same set. There are many other names of measures noted by different writers, some of which, in the explanation of some of the above mentioned, and of others it may be doubted whether they were really names of recognised measures. If the writers of our day were compared in isolated passages as closely as those of the antients, we might probably have a great many new names made for us of which we know nothing: the shells which the grocers used would have good chance of a permanent establishment, and their paper bags could not possibly escape.

The Hebrew measures, though tolerably well settled in their proportions, are very imperfectly known as to their absolute magnitudes. We shall only give here the usual summary, and shall then give some account of the mode of determining the actual magnitude of the Greek and Roman measures, to which the Hebrew measures, much have the subject received so much discussion.

The cubit was about 22 inches; four digits make one palm; three palms, or one hand, make one cubit; one hand; or one palm, make one digit; one foot; or 4 digits, make one span; 2 spans, or 8 digits, make one foot; 3 palms, or 12 digits, make one palm; 6 palms, or 24 digits, make one cubit; 6 cubits, or 12 palms, make one rod (Kaneh); 8 cubits, or 1 pole (Arabian); 90 cubits, or one measuring-line; 440 cubits, one stadium; 5 stadia, a Sabbath day’s journey; 10 stadia, a mile; 24 miles, a day’s journey.

In liquid measures, the bath, or ball, of about 44 im perial gallons, is thus divided:—Four logs make one cald; 3 cald, one hin; 2 hins, one seah; 3 seahs, one ephah. The ephah is three-fourths of the log. For dry measures, the bath, or ball, of about 16 cubic span, which is a foot, and ephahs, 5 ephahs make one letech; 2 letech, one Chomer, or Homer: the homer is the tenth of the seah.

For weight, 60 shekels make one maneh; 50 maneh, one talent of 85-97 pounds avdpurdous.

We now come to the comparison of the Greek and Roman measures with our own. The Roman foot, the most important of all, has been determined in the following ways:—1. By feet laid down on sepulchral monuments. 2. By foot-rules obtained in the ruins of Rome and elsewhere. 3. By the distance of ancient distances, such as the distance of places. 5. By specimens of the congius. 6. By some obelisks. 7. By the dimensions of buildings. The results are given in lines of 144 to the Parisian foot, and in some dissertations on this subject, the great use of the line, it will be convenient to give a table of its multiples in terms of the English inch.

The sepulchral feet are:—1, that marked on the tomb of one Statius, E* found in the Vatican garden in the sixteenth century; 2, the measure on the tomb of Cossutius (Vitruvius mentions an architect of that name), dug up in the garden of Angelo Colozzi before 1510; 3, that on the

* The *actius* is described as the length of a furrow. If our furrow had been (as some would suppose) a furrow long, it would have been nearer to the original amount of one palm and one cubit.

* The term *quadrans* seems to have applied to cubes as well as squares.

* This word is translated in two of the gospels (Mark, xiv. 3; Luke, vii. 37).
tomb of M. Philius; 4. that on a monument without inscrip-
tion, given by the Marquis Capponi to the Capitoline
Museum at Rome. Taking the means of such trustworthy
measures as have been made of these different feet, it
appears that the Statilian foot is 131-17 Paris lines; the
Cossian, or Colonian, 130-53 lines; the Capponian 131-14
lines; and the Capponian 130-80 lines.
The first foot-rule was measured by Lucas Petrus, 'De
Mensuris et Ponderibus Romanis et Graecis,' Venice, 1573,
who found three of them agreeing with each other as far as
his inspection went. On inspecting them more closely it
caused to be engraved on stone and placed in the Capi-
toline Museum. This was called the Capitoline foot, and
was frequently regarded as conclusive. Petrus himself
makes the foot-rule of a massive line, and he there-
fore supposes either that his measures are too short or that
the standard to which he referred them has been mistaken;
for others take his own Capitoline foot to be 130-5 lines.
Two other foot-rules give 128-75 and 130-03 lines. There
was a papyrus column at Rome (now lost) marked 60
which was certainly meant for nine Roman feet. An
editor of Vitruvius, Philander (1552), makes the Roman
foot to be, from this column, 131-63 lines; but Petrus
makes it only 130-03. Other foot-rules have been made
to be 130-19, 131-96, 131-27, and 130-51 lines. Some of these are
different measures of the same rule.
Very few consecutive milestones have been found from
which to deduce the foot. From one mile in the Appian
way, and from two different ones between Nimes and
Boulogne, it has been deduced that the distance is 1324-44,
129-42, 129-05, 129-31, and 129-65 lines. D'Anville, from a
collection of such measures, fixes it at 130-8 lines.
A specimen of the conquis is yet remaining, which, by
an inscription, is declared to have been placed in the Ca-
pitol by an ambassador of the Pharaohs as a standard of
the eighth part of the amphora, or cubic foot. By ascertaining
the weight of water which this contains, the foot was esti-
mated by various observers at 131-13, 133-21, and 132-44
lines. From the length of the foot drawn upon the con-
guis, certain columns at Rome (now lost) give 128-75
another conquis preserved at Paris, Austout found 134-16
lines for the Roman foot.
There are two obelisks at Rome, which were brought
by Augustus from Heliopolis. Pliny gives the height of
the taller one, but the height of the lower, the defect of the lower from it. Measurement proves that, with respect to the higher, the number of Pliny must be cor-
rect; but from his difference between the two, as compared with the measured difference, the Roman foot is 131-9 lines.
The method of ascertaining the foot by buildings is as
follows:—Any remarkable length, such as that of the whole
front of a building, being known nearly in Roman feet, is
prefixed to all these data, the number of feet which it must be
nearly. This supposes that the Roman architects were
in the habit of choosing exact numbers of feet when there
was no particular reason for breaking a foot. Raper (Phil.
Trans., 1760) proceeds in the manner of the following
instance:—He found the distances between the columns in the temple of Fortuna virilis to be 9'106 English feet. If this be an exact number of Roman feet, it
must be 10; we know enough beforehand of the Roman foot
to say it cannot be 9 or 11. Consequently, if the distances between these columns, which were not more than 10 feet, the foot must be 9'106 English feet. By processes of this sort, Greaves found 131-50 lines, La Hire 131-0 and 132-4, La Condamine 130-9, Jacquier 131-08 and 131-14. Raper, who went more into the subject, and found the distances of two columns, 131-14, 130-80, 131-62, 131-11, 131-16, 131-05, 131-16, 130-05, and 131-15 for the mean. Wurm, from the Verona amphitheatre, adds 131-12. Raper thought he observed that the buildings which were the first of Titus and some of their predecessors: from instances he gets 130-75, 130-33, 130-34, with a mean of 130-34. He refers the change to the destruction of the Capitol (where the standards were kept) in the time of Vitellius.
But a Raper's average, adopted by Wurm, is 131-15 French lines for the ancient foot, or 11-645 Eng-
lish inches, or 971 English feet. But Sir G. Shawclulgh
made a careful review of the three best modes of obtaining
the required result, namely, rules, buildings, and tombs,
and obtained 972-78, 981-61, 996-9 of a foot English. (Young's
Lectures, ii, 153.) The mean of these is 990-83 feet, or
11-196 inches. Again, if we take a mean of the results
given by others, namely, Bernard, 970, Picard and Greaves
967, Folkes, 986, Raper, 970, we have also 993-8. We
take then the Roman foot at 11-62 English inches, which
is represented fairly within the probable limits of error
by the mean of the other foot-rules. In the 17th and
18th centuries we are well aware that eminent authorities of late years prefer
11-65 inches for the Roman foot, but we like to keep as
near to the foot-rules as we can, consistently with giving
a fair standard. We are as well aware that 11-62 and
11-65 cannot be settled by authority, but must be
decided by closer approximation than has yet been made
of the probabilities of the different methods.
The Roman measures of length may thus be considered,
we fully believe, to be as well known to us as they were to
themselves. The same cannot be said of the measures of
weight. All writers agree that the amphora, or cubic foot,
weighs 80 pounds of wine; but it is also said that they
considered wine to be of the same weight as water. We
cannot venture to say how many amphorae make up some
of the specific gravities of their wines; those of our own vary from 0-99 to 1-04, water
being taken as 1. But there is one very obvious consider-
ation which, we believe, has escaped notice. No metro-
logist has given the Romans credit for seeing that water,
which is density as it is weight 1603/1000, could be measured
as weight by means of specific gravities of different
wines; those of our own vary from 0-99 to 1-04, water
being taken as 1. There is one very obvious consid-
eration which, we believe, has escaped notice. No metro-
logist has given the Romans credit for seeing that water,
which is density as it is weight 1603/1000, could be measured
as weight by means of specific gravities of different
wines; those of our own vary from 0-99 to 1-04, water
being taken as 1.
give as a mean 136-69 Paris lines, or 12-14 English inches. We may therefore say that the Greek foot was longer than the English one by the tenth part of an inch. The statements then as to the relations between the Greek and Roman measures appear to have been tolerably exact, and our knowledge of the relations between our measures and theirs, at least in regard to their comparisons, is abundantly exact for the purposes of the classical student, far more so than could have been expected to have been attainable by those who remember that for a long period all means of comparison were lost.*

The palace of the grand-duchy of Saxony—Weimar-Eisenach is situated in 51° N. lat. and 11° 20' E. long., on the bank of the river Ilm. It stands in a pleasant valley, with a wooded mountain to the north and low hills to the south and east, and a long, winding course of the river runs along the south side of the town. Weimar is one of the most remarkable towns in Germany—illustrious in the annals of German literature by the names of Goethe, Herder, Schiller, Wieland, Kotzebue, and others. It is an open town with regular streets, there are however many agreeable houses, but the general appearance is plain and rather antique. The palace is beautifully situated, and the interior is fitted up with great elegance and taste. The adjoining park would be an ornament to any country. The grounds are surrounded by the housework, the hospital, the library, the new mews, and the two churches, but none of them is at all distinguished by architecture. The Court Theatre was built in 1822, and, under the management of Goethe and Schiller, has, by the means of its financial and grandeur, contributed to improve the public taste. The grand-ducal library contains above 130,000 volumes, besides manuscripts, copper-plates, and drawings. The principal church deserves mention. In 1764, during the reign of Anna, and being adorned with several fine paintings by Lucas Kranach, particularly the altar-piece, representing the Crucifixion. The public institutions are useful and well managed. Weimar has a much-frequented gymnasium, but its chief glory is that it contains the Royal Library, which was opened in 1792, and contains 100,000 volumes. The museum, the chapel, the house of correction, an orphan asylum, a benevolent ladies' institution, under the patronage of the grand-duches, which is connected with 31 towns, and has 2500 girls instructed in female work, all over the kingdom. The establishment for destitute children was converted by the grand-duke, in 1820, into a public school for education by the name of Falck's Institution. A private establishment connected with the study of geography deserves notice, being perhaps the most extensive of the kind in Germany. It publishes maps, charts, globes, geographical works, and periodicals in great numbers. The inhabitants, now about 12,000, are of the Lutheran religion. The Roman Catholics and Jews, who are about 1000 and 500 respectively, (Catholics and no Jews), have a chapel and synagogue. There is also a chapel of the Russian Greek religion, erected for the grand-duches Maria Pavlowna, sister of the emperors Alexander and Nicholas. There are some manufactures, but they are of small importance: the inhabitants derive their chief support from the residence of the court. About two miles and a half from the town is the country-seat Belvedere, situated on a hill and surrounded with a park. There is a fine avenue from the town to this seat. [Eisenach; Saxe-Weimar-Eisenach.]

(Brockhaus, Conversations Lexicon; Hassel, Handbuch; Stein, Lexicon.)

WEIBRENNER, FRIEDRICH, one of the most eminent German architects of his time, not only on account of the numerous edifices erected and professional works published by him, but for his extensive influence as the founder of a better school of the art, was born November 9th, 1766, at Carlsruhe in Hanover, of a Protestant family (Calvinists and no Jews), and where he himself afterwards found scope for the display of his talents in the erection of a great number of both public and private edifices. Losing his father before his future destination was fixed, his studies were rather solitary, and he was left chiefly to his own impulses, directed only by the advice of his brother, who was some years older than himself. Having obtained from him sufficient insight into matters of practical routine, Weibrenner commenced his artistical Werkejahre in the spring of 1798, and set out for Zurich, where he remained a considerable time, in consequence of being engaged to superintend some timber constructions. Agreeable as his studies were, he found the acquaintances he formed with several artists and literary men—among the latter Lavater—he hastened as soon as his engagements would permit to Vienna, and after examining the architectural monuments of that capital, he proceeded to Kranach, where he had the advantage of the extent of his travels, but in Berlin he became acquainted with the brothers Genelli, architects of considerable repute and talent, who urged him to visit Italy. Their advice was seconded by Weibrenner's inclination, that though he had not been led to form such a scheme for himself, he resolved to adopt it, and accordingly set out for Rome, in June, 1792, in company with Carstens (Carstens) and another young artist named Cabot.

When the first tumultuous transport excited by the view of Rome and its monuments of art had somewhat subsided, Weibrenner felt, if not disheartened, most anxiously conscious that, in order to prove a profitable one, the study he had commenced imposed upon himself. He began to reflect what a task it would be, not only to provide for his immediate wants, which he did by giving instruction in architecture. Many strangers of distinction then at Rome took lessons of him, and among the rest was the late Henry Julius, Duke of Carlsruhe, who had been converted to Protestantism, and in Carlsruhe, he found a very promising opening for his talents. Besides being almost immediately appointed 'Bau-inspector,' he had early opportunities of displaying his professional ability in the erection of the new synagogues and one or two private mansions. Notwithstanding this favourable commencement, he gave up his appointment two years afterwards, and went to settle at Strasburg, where his wife's relations (Margaretha Arnold, whom he had shortly before married) resided, and were studied by them artists. The change however proved an important one: Strasburg became meagre by hostilities, and he found himself without other occupation or resource than teaching a few pupils. At this juncture he was invited by a gentleman, through the interest of Prince Augustus, to inspect and improve the prisons of that country. Very advantageous offers were made him to remain there, but instead of closing with them at once, he requested that he might be allowed to postpone his decision for a twelvemonth. In the interim he returned to Strasburg, and was dissuaded by his wife and her family from accepting the proposal. Fortunately he had an alternative, for he was again invited to accept his former appointment at Carlsruhe, and though the immediate returns were not considerable—not above a quarter of what he would have had at Hanover—some favourable conditions were annexed to it, and there seemed to be upon the whole a fairer prospect of his signalizing himself in this professional. He had already made up his mind that the choice of the chance, for from that period he was continually employed on various improvements and embellishments in the capital of Baden and other parts of the territory. At Carlsruhe alone he erected many buildings, especially the town-hall, the public church, the prison, the theatre, Rüttinger gate, Standeshaus, museum, mint, Hochberg palace; and at Baden the Conversations-haus or assembly-rooms, baths, and 'Antiquitaten-halle,' or museum, &c., besides the Leopold summer residence, and various other mansions, villas, &c. erected or designed by him in other places within the territory of Baden, the number is very considerable; nor are there a few by him in various other parts of Germany—Leipzig, Strasburg, Göttingen, and Jena. Being so numerous, his works display various de

* For further information on ancient weights, coins, and measures, the reader is referred to the following work: Metroglogische Unterruchungen über Gewichte, Münzformen, und Messe des Althoomers in ihrem Zusammenhang, von August Boeckh, Berlin, 1830; and to a review of this work in the Classical Museum, no. 1, by Mr. Grove.
degrees of merit according to the respective or fortunes of the past, but taken collectively, they manifest the improvement in style, with individuality of character, and fresh and masterly combinations, instead of the mere routine of design. He applied himself to his art with higher views of it than were then entertained among his countrymen, and diffused a similar feeling for it through the next generation of the profession, having reared up to it a great number of those who now rank high among the living architects of Germany. Nor was his instruction confined to them exclusively, for he published a variety of treatises, articles, and books; among other publications, two on the orders of architecture, 'Zeichnungsliebe,' 1810; 'Optik,' 1811; 'Perspektiveliebe,' 1817-24; 'Über Form und Schönheit,' 1819; 'Über Architektonische Verzierungen,' 1820-23, &c. &c. besides a work on architectural and ornamental topics in the 'Morgenblatt' and other literary journals. Though varied, his application to his professional pursuits and studies continued uninterrupted almost to the very last; for although his health began to be impaired some time before, he was taken off somewhat suddenly, March 1st, 1826, after enjoying the society of some friends on the preceding evening.

(Friedrich Weinbrenner, von Aloys Schreiber.)

WEINMANNIA, a genus of plants belonging to the natural order Cunoniaceae, and named in honour of John William Weinmann, an apothecary at Ratisbon, and author of the 'Phyntanthora Iconographia,' in four volumes.

The species are trees, and natives of South America and the Malay Archipelago. They are characterized by compound, ovate leaves, flowers in terminal panicles, and ovate, shallow, membranous calyx. The calyx is usually four- or five-lobed; the petals 4; stamens 8; and the fruit a many-seeded capsule. The flowers of the species are roundish and reniform. There are about 40 species of this genus described. The W. tintoria is a native of the Isle of Bourbon; it has leaves with many pairs of leaflets, which are oblong, serrated, and smooth-edged; the flowers are some, greenish, and multiflorous, crowded on thick, slender peduncles. The seed is roundish and reniform. This tree is called by the natives of Bourbon, Tan rouge, and is used for dyeing a red colour. Most of the species of Weinmannia possess aromatic properties, and may be used for dyeing. On this account they are also often employed in Peru to adulterate the various species of Cinchona bars which are collected for medicinal purposes. The species of Weinmannia may be easily cultivated by growing them in any rich light soil, but they do not grow in thick woods, and are only seen in this country in botanical collections.

WEIR, or WEAR, is a dam erected across a river, either for the purpose of taking fish, of conveying a stream to a mill, or of maintaining the water at the level required for the mills.

The erection of weirs across public rivers was a practice reprobated from the earliest periods of the English law, and was considered as a public nuisance. Magna Charta (c. 23) directs that all weirs for the taking of fish should be put down except on the sea-coast. By the 12 Edw. IV., c. 7, and other subsequent acts, weirs were treated as public nuisances, and it was forbidden to erect new weirs, or to enhance, straighten, or enlarge those which had aforetime existed. Hence, when a breach of weir across a river had been converted into a stone one, whereby the fish were prevented from passing except in flood-time, and the plaintiff's fishery was injured, this was considered to be a public nuisance, although two-thirds of the weir had been so converted without interruption for upwards of forty years. And it was laid down in that and other cases, that though a twenty years' acquiescence might bind parties whose private rights only were affected, yet that no length of time can extinguish public rights or legal duties. See Smith's 'Pract. of Eq.' p. 1566; Giffard v. Alds. 662.) On the same grounds it will probably be held that the Prescription Act (2 and 3 Wm. IV., c. 71) does not apply to weirs. It appears therefore that no weirs can be maintained in an interference of the rights of the public, or even, as it seems, of individuals, except such as have existed time out of mind, or such as have been erected under local acts of parliament for the navigation of particular rivers.

WEISSE, CHRISTIAN FELIX, was born on the 8th of February (28th of January, Old Style), 1729, at Anna-
berg, in the present kingdom of Saxony. His father, Christian Heinrich Weisse, was a member of the public grammar-school at Annaberg, and from 1727 directed the gymnasium at Altenburg, was a distinguished scholar, whose works, 'De Stylo Romano,' and 'Latium in Compendio,' were much esteemed in their time. Young Weisse lost his father at an early age, and, having finished his preparatory studies in the gymnasium at Altenburg, he went to the university of Leipzig in 1745, where he studied the classical languages and antiquities under Ernesti. At Leipzig he became acquainted with Lessing, who directed the 'Theater,' and having there given the 'Burleith,' and the 'Lieder von Ephesus,' till 1767. In this year he published 'Die Befreiung von Theben' ('The Deliver of Thebes'), which was his first drama written in blank verse. He felt that the Alexandrine, in which the German dramas were generally written, were, among other causes, the chief foes of the German school, the worst of all, and the principal cause of the tedious monotonous of the dialogue. When he abandoned this verse at the suggestion of Lessing, and adopted the blank verse of the English drama, he was enabled to do it, as he thought, at a single blow. The 'Rheinische Morgenblatt' says: 'Weisse was thoroughly able to conceive any great passion; for each passion he had one mould, such as the character of Nero, of Alexander, of Medea: he was unable to depict the same passion with any variety, and the only difference between his dramas is their tone. Weisse was thoroughly and almost a mere poet: he was thoroughly the tragedian; he was thoroughly the man of genius, and he was thoroughly the poet. Weisse was himself in the theatre of the world; he had no periods, and he had no scenes. He was himself a whole mass, he was himself an entire passions. He was himself the representation of the character; and when he entered a stage, it was entered with the character; and when he left the stage, it was left with the character.'
amusements of the children, their education, the various branches of their instruction, and their amusements, are described: a great number of tales are introduced, which they are supposed to tell to one another; and several little comedies, which the members of the family perform for the entertainment of their friends. From 1775 to 1782 the "Kinder-Freund" went through five editions, among which two are in twenty-four volumes, and three in twelve. The "Kinder-Freund" was continued in the "Briefwechsel der Familie des Kinderfreundes," 12 vols. 8vo., Leipzig, 1783-88. Lippert, for reputation, "Kinder-freund," to two parts a translation. There is a large biographies, and in several parts a translation. Weisse's works for children have not been translated either entirely or in extracts or abridgments. Weisse's literary activity was immense, and lasted till his death, although by a fall from a ladder in his library, in 1792, he almost lost the use of his hand, and was obliged to dictate. He published many translations from the English, especially works for the use of children and young persons of both sexes, such as the works, or parts of the works of Richardson, Law, Moore (the Fables), James Fordyce, Brooke, Scudéry, and others, in a very pretty and even beautiful style, as of Dryden, Pope, Congreve, and many other works. The reputation of Weisse from the time that he began to write for children was very great. However in all his works on education there are indications that the author's system was rather a continuation of the teachings of Rousseau and Voltaire than the formation of his character. His real merit is nevertheless great. Though unable to throw off the false rules of a taste in which he had been brought up, he was an enlightened man, of extensive knowledge, and a good judge of things. Of late he has often been severely criticised, but his contemporaries held him in high esteem. Wieland dedicated to him his "Musurion;" Thimmel, his "Inoculation der Liebe;" Gerbelberg, his "Die Braut;" Rastatt, his "Der Teufel," a work in 1801, and his "Schadet und Nutzen," a work in 1808. Dyk, whose "Essays on the Character of Zollikofer," and the second volume of his "Versuche über Gegenstande der Moral und Literatur;" Teller, his "Darstellung der Sprache in Luther's Bibel-Uebersetzung;" and Eichstädt, his "Verhandlungen der deutschen Literatur," dedicated themselves to Weisse for the revision of his works: as Winckelmann for his "Geschichte der Kunst des Alterthums;" and "Ueber die Baukunst der Alten;" Hagedorn, for his "Betrachtungen über die Malerei;" Lippert, for his "Betrachtungen über die Malerei;" Berlin, a medal in memory of Weisse, for which Frisch made the design and Ramler wrote the inscription.

Weisse died on the 18th of December, 1804. The principal editions of his works are: 1st ed. Leipzig; 3rd ed. Leipzig; 1st vol., 3rd ed., 1771; 2nd vol., 2nd ed., 1767; 3rd vol., 2nd ed., 1768; 4th vol., 2nd ed., 1769; 5th vol., 2nd ed., 1769; 2, Trauerspiele, 5 vols. 8vo., Leipzig, 1776-80. Several of his tragedies were published separately, as his "Der Teufel ist los, 1st part, 1770, 2nd part, under the title 'Der lustige Schuster, oder Der Teufel ist los,' 1771, fol., &c.; 5, 'Kleine Lyrische Gedichte,' Leipzig, 1772, sm. 8vo.; the songs for children are contained in the "Kinder-Freund;" in the "Kinderfamilie," edited by the "Geschichte der Schönheit des Freundschafts," 12 vols. 8vo., each containing 2 parts, 1790-76. This work was very important for the literary history and the biography of the scholars and writers of Germany, and was published in Europe. During his residence in the eighteenth century. A catalogue of the biographies and articles contained therein was published at Leipzig in 1767. Weisse, as already observed, was the editor of this work from 1760; his editorship began with the fifth volume. The number of his contributions is very great; his criticism of Wieland's translation of Shakspeare is remarkable. The work was continued under the title, "Neue Bibliothek der Schönen Wissenschaften und freien Künste," 72 vols., Leipzig, 1756-1806; the latter part of which was edited by Weisse and Dyk, the learned publisher of the work, who, after the death of Weisse, was the sole editor. The "Bibliothek der redenden und bildenden Künste" is a continuation of the "Neue Bibliothek," &c.

A complete catalogue of Weisse's works and other literary productions is given by Jürgens. In 1830 a school for girls was established, for the children under the name of Weisse's-Stiftung (Weisse's Institute). Weisse was married to a sister of the celebrated philosopher Platten.

Some further biographies: Ebner, who was born in 1765, became professor of feudal law, and afterward of law at Prague. He died in 1832. He was a distinguished jurist; consult the old historical school, but was unable to keep pace with the ideas of the nineteenth century. His principal works are: 1, "Geschichte der Kur-Sächsischen Staaten," 4 vols. 8vo., Leipzig, 1802-6, the continuation of which is, 2, "Neueste Geschichte des Königreichs Sachsen seit dem Frieden_Plattner;" 3, "Museum für sächsische Geschichte, Literatur, und Staats-Kunde," 3 vols. 8vo., Leipzig, 1794-96; the continuation of this work is, 4, "Theatrum Saxonum," 5 vols. 8vo., Leipzig, 1792-93, an excellent collection of documents and other materials for the history of Saxony. 5, "Lehrbuch des Sächsischen Staatsrechts," 2 vols. 8vo., Leipzig, 1809.

Weissenfels is a garrison town, has 4 gates and 4 suburbs, and on a rock outside of the walls stands a large castle, now converted into barracks. In the convent church, which is no longer used, are deposited the remains of several princes, and also those of the great Gustavus Adolphus, king of Sweden, who fell in the battle of Lützen, Nov. 6, 1632.

"Müller, "Wörterbuch des Preussischen Staates;" Hassel, "Die Preussische Monarchie" (in his Handbuch).

WELDON, JOHN, one of our most eminent composers of cathedral music, was born at Chichester, and studied his art under the famous Henry Purcell. At an early age he became organist of New College, Oxford; in 1749, he succeeded gentlema...
The friend of the composer is mainly built on his anthems; 'In Thee, O Lord,' and 'Hear my crying,' of which Hawkins justly observed, 'it is difficult to say whether the melody or the harmony of each is its greatest excellence.' Dr. Burney speaks slightingly of Weldon's powers; and it is probable that on this subject he was either prejudiced, or interfered and associated with the works of others not so critically.

Weldon died in 1736, and was succeeded in the chancelroy by Dr. Boylee. (Harmonicoxi, xi. 117.)

WELLS, WELLESLEY, RICHARD COLLEY, MARQUESSE OF

The first act of the young Lord Mornington, on attaining his majority, was to assume the numerous pecuniary obligations of his father, and place his fortune under the management of his mother. Encouraged by the reputation he had acquired with his teachers and schoolfellows, he selected political pursuits as the means of starting him in a career which would enable him to render himself useful to the family. With this view he took his seat in the Irish House of Lords, as soon as he had come of age, and continued a member of that body till the Union. This proved however too narrow a theatre for his abilities or his ambition. He kept up the English connections which he had formed during the time of his education, and having been returned a member of the British House of Commons by the borough of Bealston, became a frequent visitor in London. On his first opportunity he had of attracting substantial notice occurred during the regency debates of 1789. The British Houses of Parliament, on the illness of George III., proposed that the Prince of Wales should assume the office of regent subject to certain conditions or restrictions, which the House of Commons declared should be unrestricted. The earl of Mornington strenuously supported restrictions in the Irish House of Lords, maintaining that the full powers of the crown should not be assumed by any one during what might prove a temporary interregnum of the British throne. These views, which coincided exactly with those of George III., induced the king, whose attention, after his recovery, had been called to the minorities in the Irish Houses of Parliament, to take as his guide the young statesman. He found the toils of one legislative body too little for his activity. At the next general election the earl of Mornington was returned for the borough of Windsor, sworn in a member of the Irish privy council, and elected one of the knights of St. Patrick.

He was soon after appointed one of the lords of the treasury, and in 1793 he was sworn in a member of the British privy council. He continued to make such steady progress in the favour of the king and the confidence of the minister, that he was nominated to succeed Lord Cornwallis in the government of the East India Company at this time to the British people by the title of Baron Mornington. The marquises which he subsequently received was merely an Irish title. As a British peer he was never raised to a higher rank than that of baron.

He was placed in the government of India on the 4th of October, 1779; he reached the Ganges in May, 1789, after touching at the Cape of Good Hope and the Isle of France by the way, having some time before been preceded by his brother, Colonel Arthur Wellesley, which displayed the high condition of Saipan. He retained the supreme command in India till August, 1805, when he embarked to return to Europe.

The governor-generalship of the earl of Mornington, or, to use the title by which he is best known, the governor-generalship, was the occasion of the government of the east India Company and the new circumstances which were forced the Nizam to disband his French troops; the next was to open negotiations with Tippoo, in order to detach him from the French alliance. Failing in this, and having detected Tippoo's negotiations with France, the English armies were made by the Indian government to organize the Native and improve the British troops. With his characteristic promptitude of decision, the governor-general resolved to strike home at once. Warlike operations commenced with the victory of Brillant, which displayed the high condition of Anglo-Indian army. Following up this impression, General (afterwards Lord) Harris was ordered to invest Serings-patam, which, after a siege of a month, was taken by assault, and the Sultan slain. His territories were partitioned. The capital with the principal towns, including the fort of Mangalore, was retained for the East India Company; compensation was made to some native allies; and the remainder of Tippoo's territories, with the nominal sovereignty over the whole, was restored to him in the presence of the victorious army, as a child of five years of age. So complete was the effect of these victories and the subsequent arrangements in impressing the minds of the natives with a sense of the strength and resources of the Anglo-Indian government, that General Wellesley (in one of the works published by Colonel Gurwood) writes to his brother, that he only waits to know what countries they are which the governor-general wishes to take possession of.

The next efforts of Lord Wellesley were directed to the extension of the commercial intercourse of India, and to the commencement of those important financial reforms which eventually raised the revenue of the Company from seven millions to upwards of fifteen millions annually, envied by no one, and to communicate intelligence to the inhabitants. His projected extension of the commerce of India was in part thwarted by the monopolist spirit which at that time prevailed among the directors of the East India Company. Nowise cooled in his zeal by this disappointment, he prepared a scheme of the reorganization of the British empire in Asia, and to establish it on a broader basis. With this view he undertook a vice-regal progress through the northern provinces, visiting the native princes with a pomp equal to their own, redressing grievances, checking enemies, and conferring favours upon the inhabitants.

In 1801 he was again involved in warlike operations. He in that year despatched a considerable force up the Red Sea to assist in wresting Egypt from the power of France. He next turned the British arms against the Morbucks, and, after a severe struggle, conquered the whole country between the Jumna and the Ganges, and compelled Scindiah and the Rajah of Berar to make
peace. Sir Arthur Wellesley's victory of Assaye and the crowning battle of Lascarswaran terminated a war directed with an energy and fertility of resources that gave good and true augury of the future career of the commanding officer on a more important and conspicuous field. Without undervaluing the political wisdom of the Marquess Wellesley, it may safely be said that he had not possessed so able a general as his brother, the result of the war might have been less favourable; and that, had it been less favourable, his policy would have been judged of very differently from what it has been.

After six years' service in India, the Marquess Wellesley became desirous of returning to England. Such however was the estimation in which his services were held at home, that some years elapsed before he pronounced his intentions to apprise them of his intention to obtain the release he solicited. At last he was allowed, in 1805, to resign the government of India, and he embarked for Europe in the month of August. He was received with every demonstration of respect and approbation by the government and the East India Company. Complaints were indeed heard that his administration had been unwarrantably expensive, and that he had been guilty of oppression towards the native powers, especially the Nabob of Oude. Articles of impeachment were presented against him by the House of Commons, but he resisted the charge, and was acquitted. The charge was that he had procured the death of Mr. Paull. But the judgment of the public then (and the time which has since elapsed, with all its gradual disclosures, has only confirmed that judgment) was, that without adopting all the exaggerated eulogies of the partizans of the Marquess of Wellesley, the circumstances of our Eastern empire, the wisest and most just that could have been adopted. His government marks the commencement of a better era of English rule in India.

The Marquess Wellesley on his return from India again took part in the proceedings of parliament. He had no great sympathy with the opposition; that could scarcely be expected from one who might almost be regarded as the first one of all who were interested in the welfare of a strenuous supporter of Mr. Perceval's government, or even, at a subsequent period, of Lord Liverpool's. The Pitt party had been disorganized by his death at the time that Lord Wellesley returned from India, and it was not again consolidated until Lord Liverpool was placed at the head of affairs. Besides, the Marquess's position as governor of a distinct empire, and his protracted absence from England, had impressed him with a feeling of personal consequence which ill qualified him to perform a subordinate part. He perceived that his views were at variance with those of his brother, and to a great extent emancipated his mind from the mere party contaminations of this country. He so far concurred with the general policy of administration that he was a zealous advocate of the war against Bonaparte which were destined to muzzle with narrow-minded and oppressive views in home politics; although, bred under Mr. Pitt and matured in India, he cared little for the constitutional views which were then popular.

In 1807 Lord Wellesley evaded the argury of the king, who wished him to become a secretary of state in the duke of Portland's cabinet. In 1808 he rendered ministers efficient service by his vindication of the expedition to Copenhagen. He was soon after advanced to the ambassadorship to Spain. A short residence in Spain convinced him that, if Bonaparte were to be driven out of the Peninsula, it must be by Britain ceasing to play the part of a mere auxiliary, and taking the lead in the war. On the death of the duke of Portland, he was appointed lord-lieutenant of Ireland, and was supported by the king to accept the appointment of secretary of state for foreign affairs with Mr. Perceval. He held his office from December, 1809, till January, 1812, when he resigned on account of the difference of opinion existing among the cabinet on different points, especially respecting the Roman Catholic claims and the inefficient conduct of the war.

After the assassination of Mr. Perceval, in May, 1812, Lord Wellesley undertook, at the request of the king, to form a new cabinet. Such a task is alike difficult and unprofitable; when party distinctions are becoming obsolete, parties may be fused with advantage; but coalitions, which are alliances of parties, each retaining its distinctive character, when effected necessarily draw loss of respect and influence along with them. The distinction between the parties of that day was still too strongly marked to admit of their being fused together, and their leaders were too wise or too fond for a coalition. In three days Lord Wellesley saw that the undertaking was hopeless, and resigned his charge.

On the 6th of June, Lord Wellesley announced in parliament that he was at the head of the government. On the 1st of July Lord Wellesley brought forward a motion favourable to Roman Catholic claims in the House of Commons, similar to that which was moved a few days earlier in the House of Commons. It was lost by only one vote, and that vote a proxy. He continued for ten years from this time to offer a modified opposition to government. During the Peninsular war he had repeated in his speeches for the indemnity to the India Company, and his brother. In 1815 he condemned in unqualified terms the disregard to commercial interests that marked the treaties by which the peace of Europe was consolidated.

In December, 1821, he accepted the appointment of lord-lieutenant of Ireland, an office which he continued to hold till March, 1828. The nomination of the Marquess Wellesley, a well-known advocate of the Roman Catholic claims, to this high office, raised on the one hand the expectations of the professors of that religion, and excited on the other great excitement in the opposition party. His arrival was the signal for an outburst of the fiercest party spirit. The Orangemen of Dublin insulted the lord-lieutenant in the theatre, and the southern counties became the scene of insurrectionary movements. The viceroy commanded Sir John lickey to adopt a conciliatory policy, but the times did not admit of its being followed up. It was deemed necessary to have recourse to an Insurrection Act and other coercive measures. Yet the provincial chiefs of the Marquess Wellesley continued to command respect; his impartiality and kind disposition escaped impeachment. The Earl of Liverpool's retirement from public life had no effect upon the position of Lord Wellesley, for both Mr. Canning and Lord Goderich were ready to accede to his propostions. But when the Duke of Wellington came to assume the reins of government, the first declaration which he made upon the subject left the lord-lieutenant of Ireland no alternative but to resign.

On the formation of the Grey ministry the Marquess Wellesley accepted office under it. In 1831 he was appointed lord-steward. In September, 1833, he resigned that office, and was once more appointed lord-lieutenant of Ireland. On Sir Robert Peel's brief administration (1834-5), he resigned the government, though urged by his brother to remain. He accepted the office of lord-chamberlain on the formation of the second Melbourne ministry, in April, 1835, but resigned it in the course of the year, and was afterwards appointed to the House of Lords.

He died at his residence, Kingston-house, Brompton, on the morning of Monday, the 26th of September, 1842, in the 83rd year of his age.

The Marquess Wellesley was twice married. His first wife, Hysacine Gabrielle Roland, was married to him on the 1st of November, 1794. They had had several children who died young, but none after marriage. They separated soon, and were not again reconciled. The first Lady Wellesley died in 1816. On the 29th of October, 1825, at the advanced age of 65, the Marquess Wellesley married for the second time. His wife was an American lady, daughter of Mr. Richard Caton (granddaughter of the eminent revolutionary patriot Carroll of Carrolton), and widow of Mr. Robert Patterson. By this lady, who has survived him, he had no children.

Lord Wellesley's character was simple, frank, and of enlarged views. His administration in India was brilliant and productive of lasting good; though part of the credit must be attributed to the high cast of official talent developed in the East India Company. His arrangements of that body, and part to the efficient assistance he derived from his brother and the other generals in the field. The marquess was an elegant scholar, of a disposition too delicate to stand the ruder shocks of parliamentary warfare. His prosperous career, more flattering to his ambition than productive of emolument. His father's debts were paid by him voluntarily, but he was unable to preserve the family estates. In 1857 the directors of the East India Company passed a resolution to the effect that they had reason to believe the
Marquess Wellesley was involved in pecuniary difficulties, and that therefore they deemed it their duty to offer him some further acknowledgment of his distinguished services. The resolution proceeded to state that, on the fall of September, the sum of 150,000l. was set apart for the Marquess Wellesley—a grant which on his suggestion was abandoned to the army. It was afterwards determined to vote him an annuity of 5000l., which had ever since been paid; but the Court of Proprietors believed that the Marquess, by the advances he had made to the grant, and under these circumstances it was resolved that the sum of 20,000l. be placed in the hands of trustees for his use and benefit. This grant his lordship accepted.

Some Latin poems by the Marquess were published early in 1835, a thin 8vo., published in London, purporting to be a history, by the Marquess, "of all the events and transactions which have taken place in India during his administration." It is a mere translation, from a French version of some of his intercepted despatches, published at Paris. In 1836 Mr. Montgomery Martin published, in five volumes, 8vo., at the expense of the East India Company, 'Despatches, Minutes, and Correspondence of the Marquess Wellesley, during his Administration,' in a thin 8vo. volume, re-published, in a thin 8vo., from parliamentary papers, 'Despatches and Correspondence of the Marquess Wellesley, during his Mission to Spain.' His lordship also published a number of occasional pamphlets:—"Substituting the House of Commons on the House of Lords, in 1794;" "Notes relative to the Peace concluded with the Maharrats;" "Letters to the Government of Fort George, relative to the form of government established therein;" "Letters to the Directors of the East India Company, on the subject of the Mahratta rebellion." This sketch has been compiled from the publications mentioned above; the 'Annual Register,' and the 'Parliamentary Debates,' and from a memoir of the Marquess Wellesley, which appeared in the 'Times' newspaper soon after his death.

WELLS, PROVINCE OF [PENANG.]

WELLSBOROUGH. [NORTHAMPTONSHIRE.]

WELLINGTON. [SHROPSHIRE.]

WELLINGTON. [SOMERSETSHIRE.]

WELLINGTON. [ZEALAND, NEW.]

WELLS. [ARTESIAN WELLS; SPRINGS.]

WELLS, MINERAL. [WATER, p. 111.]

WELLS, an ancient city and bishop's see, and parliamentary borough, 120 miles from London, in the hundred of Wells-Forum, in the county of Somerset. It is situated in a valley at the foot of the Mendip Hills, near the source of the river Ax, and also near that of another spring, called St. Andrew's Well, from which the initial of the town's name is derived. It was nearly all the town, which is situated in a distance nearly all round the city. The founder of the first church at Wells is said to have been Ina, king of Wessex, in 704. In the reign of Edward the Elder, in the beginning of the 10th century, the town was a bishopric. About 1091 John de Villula, who, by the practice of physic at Bath, and by other means, is said to have earned the means of purchasing the see from William Rufus, obtained the bishopric, and removed the episcopal seat to Bath, and called himself bishop of Bath only. This led to bitter disputes, which were settled by Bishop Robert, the successor of Villula, who, about 1139, determined that the diocesan should be styled bishop of Bath and Wells, and be enthroned on his admission in both churches. He was archbishop of York, and on his death, his successor had already gone to decay. In 1202 King John granted a charter erecting the town of Wells into a free borough, constituting the men free burgesses, and granting a Sunday market and five annual fairs. The governing council of the borough, up to the time of the passing of the Non-John Corporation Act in 1835, was the 31st of Elizabeth, under which corporation, a self-elected body, consisted of a mayor and recorder, seven masters or aldermen, sixteen common burgesses, and an indefinite number of burgesses. In 1835 the number of freemen was 460, and the mayor, recorder, and senior master acted as justices for the borough. The remodelled corporation consists of four aldermen and twelve councillors, and the number of burgesses has been reduced to an indefinite number of burgesses. In 1835 the number of freemen was 460, and the mayor, recorder, and senior master acted as justices for the borough. The income of the corporation in 1840 was 1088s., of which 517l. arose from borough and gaol rates; 149l. from tolls and dues; and 170l. from rents and fines on renewal of leases. The borough expenditure for the same year was 1305l., of which 17l. was for police and constables; and 600l. for public purpose. The amount of borough rate levied was 442l.; and in the same year there were 343l. levied under local acts. The corporation was 1700l. in debt.

The limits of the borough have been extended, so as to comprise the actual city and suburbs, and they now coincide with the limits of the parliamentary borough, which were enlarged when the Reform Act was passed in 1832, but only include that part of the out-parish of St. Cuthbert, adjoining the city which is built. The number of borough voters on the register in 1839-40 was 414: in 1837 there were 103 freemen, who were not burgesses, though they were entitled to vote for the members of the city. Wells has returned two members to Parliament since the reign of Edward 1st., and the Reform Act made no alteration of the number.

The city is situated in a large parish called St. Cuthbert, which contains many hamlets, and extends in every direction beyond the city: the parish of St. Andrew, which comprises a few persons only, is entirely living in it than there were 23 years before. The silk trade had been wholly given up, but there was still one large stocking manufactory, which, within the two preceding years had employed as many as 1500 persons. The town still stands on one side of an extensive market, as is commonly held the place of the cathedral close. The cathedral, which is one of the finest structures of the kind in England, forms a striking object as seen from all the great roads leading to the city. It is in the usual form of a cross, the principal limb or bar, which extends from east to west, is 371 feet in length, and the transept measuring 135 feet from north to south. The tower, which is over the junction of the nave and transept, rises to the height of 160 feet from the floor; and two other towers measure the same height, crossing the extremities of the west front. This façade is remarkable for its tracery and sculptured figures: there are about 150 statues of the size of life, and above 300 others of smaller size; and although many of them are a good deal mutilated, the effect is very striking. The present cathedral was begun in the early part of the reign of Henry III. (1216-1272) by Bishop Joceline de Welles, who also made Wells his place of residence, and in other respects restored it to the precedence which, on everything below except the west end, it had once enjoyed. The entire body of the church, from the west end to the middle of the present choir, is supposed to have been the work of this bishop. The two western towers were added about the end of the 14th century, that at the eastern end, the choir, and the western tower, the north by Bishop Butwth, twenty years later. The church had been previously completed to its eastern extremity, and the great central tower erected, soon after the completion of the last. The three towers, which are so well placed that the glory of Wells cathedral, and by many it is said to be the most beautiful specimen of ecclesiastical architecture in England. There are several antient and other remarkable monuments deserving of notice. The clonsters of Wells, which stand in a quadrangle within the cloisters, the sides severally measuring from 150 to 160 feet. The chapter-house is a handsome octagonal building, 52
feet diameter in the interior, the roof being supported by a single central pillar. The episcopal palace stands at a short distance south from the cathedral, and with its lofty and embattled wall, enclosing an area of about seven acres, and surrounded by a broad moat filled with water, resembles an old baronial castle. The deanery-house is north-west from the cathedral, and beyond are twenty houses called the Vicar's College or Close, an establishment consisting of the dean and chapter, and of the college, of which the dean, and chapter, of the great annual income of 698£, net annual value 564£. The Independents, Methodists, and Baptists have places of worship: the number of Sunday-school children belonging to the different denominations in 1833 was as follows:—Church, 122; Independents, 90; Methodists, 43; and Baptists, 40. The endowed charities are numerous, and in 1840 they amounted to 1853£, administered by nine trustees. The principal are an almshouse for forty men and women, and a hospital for seven almshouses on a smaller scale; two schools, called the Blue Schools, for 34 boys and 20 girls, twenty of each being clothed, the boys apprenticed, and an outfit being provided for the girls on going to service or otherwise entering upon some occupation; a grammar school for boys supported by the dean and chapter, who allow the master a salary of 30£ a-year, with apartments, and a school-room in the cathedral cloisters. In 1829 an infant-school was established, which in 1833 was attended by 52 males and 53 females.

The market-days are Wednesday and Saturday; and there are fairs in May, July, October, and November.

(Contribution to History of Somersetshire, vol. i.; Britton's Catalogue of the British Museum.)

WELLS, CHARLES WILLIAM, physician, was born at Charleston in South Carolina, in May, 1757. His father and mother were natives of Scotland, and emigrated in 1733. He was sent by his father to Dumfries and afterwards to Edinburgh, where he was apprenticed to a surgeon. He returned to Carolina in 1771. The revolutionary movements shortly after commenced in America, and his father, who espoused the royalist party, was obliged to flee to Great Britain, where he was followed by his son in 1775. He then went to London and commenced practice as a physician in 1783. In 1790 he was appointed physician to the Finsbury Dispensary, and in 1795 was elected assistant-physician to St. Thomas's Hospital, and full physician in 1800.

Dr. Wells was a fellow of the Royal Society, and published a number of the 'Transactions.' In 1796, 'On the Influence which incites the Muscles of Animals to contract,' in M. Galvani's 'Experiments.' 2. In 1797, 'Experiments on the Colour of the Blood.' 3. In 1811, 'Experiments and Observations on Vision.' In the 2nd and 3rd volumes of the 'Transactions of a Society for the Promotion of Medical and Surgical Knowledge,' he published several papers on various departments of medicine. His contributions to newspapers and magazines were very numerous, and he was a man of clear and judicious thought and arguments. His last work, and the one on which his reputation as a philosopher must rest, is his 'Essay upon Dew,' which was published in 1814. The demonstration of the nature of dew in this work is an extremely fine application of the principles of philosophical botany, and is deservedly given the author a wide-spread reputation. The experiments involved in this inquiry were such as to lead him to expose himself frequently for long intervals to together to the night-air. The consequence was, that it brought on attacks of disease from which he never ultimately recovered, and he died on the 18th of September, 1817. Mr. Wells was an accurate observer and an acute reasoner, and all his productions bear marks of a superior mind. In an edition of his works published in 1821 is an autobiography written a short time previous to his decease, from which this notice has been chiefly taken.

WELSH LANGUAGE AND LITERATURE.—Literature. The Welsh language is that which is now spoken, and has been so far back as historical records extend, in the principality of Wales. The name of 'Welsh' was first given by the people who speak it by the Anglo-Saxons, and the same term or a similar one seems to have been used by the Germans, the Saxons, and the Slavonic languages to denote the Italians, or other nations whose languages resembled the Latin. 'Welschland' was the name for Italy in several of the middle ages, and is still perpetuated in the languages of the common people; the name of that country in Polish is 'Wlochy,' and the appellations of the Walloons and the Wallachians are derived from the same root. The Welsh are probably indebted for the name to the Saxons as subjects of a Roman province.

The name which the Welsh give to themselves is 'Cymry,' and to their language 'Cymreig,' the obvious resemblance of the sound of which to 'Cumbri' has led many to identify them with the Celts. The Roman conquerors were convinced that the language was not that of a Celtic nation by any means, as is shown by the fact that they never ceased to write in Latin; and the educated opinion however with regard to their origin is that they are a Celtic tribe, and of the same blood and language as the native Irish and the Scottish Highlanders. They claim the appellation, and are but arguing for their language the honour of having been the first spoken in this island, which they support, among other grounds, by the signification of the word 'Cymry,' which is said to denote 'primitiveness.' It is probable that most of these appellations are well founded, but it is certain that there is no necessity for doubt, but nearly all are subject to some degree of doubt, and all have been warmly contested of late years, during which more attention has been directed to the subject. The meaning now affixed to the word 'Cymry' does not appear to have come into the language until the end of the eighteenth century. Even the claim of the Welsh to the appellation of Celts has been disputed. Their having been the primitive inhabitants of Britain is denied by Sir William Betham, who contends that the earliest known spellings of places in England can only be satisfactorily derived from the Gaelic or Irish, and that the Welsh are a foreign tribe, the Beige of Casar, who had only made his appearance after the battle of Mons Meg, which was fought before the date of Caesar's own invasion. In the 'Gentleman's Magazine' for June, 1843, a work is announced by the Rev. R. Williams of Llangawadlais, 'Dictionary of the Antient Cornish Dialect of the Celtic, with the Synonyms of the Welsh.' In which the Welsh have been made to prove that the antient names of places, not only in England, but in Scotland and Ireland, are clearly derivable from the Welsh, and that therefore the Welsh were the original inhabitants of all these countries. The most singular dispute however that has arisen connected with the Welsh language is that on the affinities between it and the Gaelic and Erse. The general and almost undisciplined opinion for a long time had been that the two languages were dialectical forms of the same original language, and a connection between the two, or the Gaelic and Erse, was hinted at by the name of 'Cymry,' which means in an animated correspondence on the subject, which was carried on in the 'Gentleman's Magazine' for 1836 and 1838. The main fact which he announced, that the most intimate knowledge of the Gaelic language would not enable him to pronounce a single word of it, since he was, as he asserted, a new to people in general, and would never have been suspected from the tone in which most Celtic scholars were accustomed to speak of the affinities of languages; but the inference which he drew from it, of a total want of connection between the two, was not refuted by other facts. The Rev. Richard Garnett, of the British Museum, who was induced to search into the question by the statements of Professor Forbes, reports in the
The Welsh language in its present state is one of the oldest in Europe; it is in fact among spoken languages the most antient of which any written monuments are preserved, unless we regard the latter as to certain degrees the antient Greek. The Welsh has poems now in existence, the origin of which is referred with probability to the sixth century. It is true that the language of these is so antiquated that the best scholars differ about the interpretation of many passages, and yet we find that in Price’s ‘Hanes Gymru,’ it is deemed proper to subjoin a modern version even of a poem by Gwawchsai, in the twelfth century, for the information of the common reader, but, generally speaking, the body of poetry which the Welsh has preserved is more probable to be of later date. In Stewart’s ‘Grammar’ we have a list of twenty-four simple prepositions (omitting mere varieties of form), and about forty improper, or compound. Of the former, fourteen are Welsh, and three Cornish; and of the latter, eighteen, or nearly one-half, radically Welsh. Mr. Griffith adds with justice that ‘the amount of resemblance is hardly so great between Icelandic and German,’ and these are unquestionably cognate languages.

On the whole, therefore, it may be stated that the Celtic languages consist of two distinct branches, the first comprising the Irish, the Gaelic, and the Manks, which are in fact merely dialects—all three intelligible to any person who is master of one; and the second comprising the Bretonic or Gallic, and the Celtic. The affinity between the members of the latter branch is not so close as that between the members of the former, or so close as it has often been asserted to be. The best evidence on this point is that of the Rev. Thomas Price, a distinguished Welsh scholar, who in the year 1820, published a very entertaining and instructive narrative of it in the ‘Cambrian Quarterly Magazine.’ ‘I may,’ he says (‘Cambrian Quarterly Magazine,’ vol. ii., p. 197), ‘be asked a question which I have of myself have proposed to another, whether I have ever visited Brittany, and that is, if the Welsh and Breton languages bear so near a resemblance to each other as is generally understood, where was the necessity of having recourse to the French as a medium of communicating words? The Welsh is now and always was connected with the French in the Welsh at once? To this I answer that, notwithstanding the many assertions which have been made respecting the natives of Wales and Brittany being mutually intelligible through the medium of their respective languages, I do not hesitate to say that the thing is utterly impossible; single words in either language will frequently be found to have corresponding terms of a similar sound in the other, and occasionally a short sentence deliberately pronounced may contain two or three words of the same sound in both languages, but as to holding a conversation, that is totally out of the question.

There have been numerous unfounded statements with regard to the affinity of Welsh to other languages than those which have been enumerated as composing the Celtic stock, the most of which have been derived from having been divested of the writer’s peculiar orthography, which, whether preferable or not to the common system, was a serious obstacle to the learner. It is still considered by many a convenient for use in English. The number of words is swollen to about 100,000, but the twelve thousand quotations which it contains, accompanied by translations, form an invaluable feature. This dictionary comprises Welsh and English only, not English and Welsh. The Welsh language is distinguished for the beauty of the compounds, which it possesses the capacity of forming to an almost unlimited extent. It has often been praised for this peculiarity. The latter part of the word is its general character, as it is now written, is that of tameness and diffuseness. Many of the phrases most constantly occurring require a greater number of words to express them in Welsh than in English. The most remarkable peculiarity is the way in which the initial letters of certain words are changed when they follow certain other words. Thus ‘ei’ in Welsh signifies ‘a dog.’ To signify ‘my dog,’ it is necessary to say ‘v y ngh,’ not only prefixing the word ‘vyr,’ or ‘my,’ but altering the initial ‘ei’ into ‘egh;’ for ‘thy dog,’ the expression is ‘v yr eg.’ For ‘my head’ beginning with a different letter undergoes a different mutation. ‘Pen,’ a head, is changed into ‘v nhyn,’ in indicating...
The use of a language so different from English by a portion of the inhabitants of the country has often been considered an evil, but no active measures appear to have been taken against the peculiar speech of Wales. The fear of a progressive extinction of the language, if not of mere neglect, has led to the supposition that the Welsh would also disappear from the same cause; and indeed Mr. Wynn, the president of the Asiatic Society, has considered the necessity of a systematic attempt to save the language from the danger of its extinction as a proof of the efficacy of the system of such cases, in a discussion on the subject of endeavouring to introduce the English in the place of some of the native languages of India. The same idea was prevalent a century or a hundred years before, when the translator, the poet, relates in one of his letters (printed in the 'Cambrian Register,') that in a discussion on the Welsh language with another Welshman, Owen, the translator of Juvenal into English, 'the wicked imp, with an air of compunction and regret, refers to the glory of the Myrwyrian Academy, and his own reading, and that to his certain knowledge the English daily got ground of it, and he doubted not but in a hundred years it would be quite lost.' The hundred years that have since elapsed have not confirmed this opinion. 'The language,' says Dr. Owen in an address delivered in 1821 on the formation of the Cambrian Society in Gwent, 'since the reign of Offa, who made his celebrated dyke to prevent incursions of the Welsh into his territories, the Welsh language has receded completely from a part of the soil of Cymru, and some parts of North Wales; and in other districts, where the long lapse of time since the conquest by Edward I. and the intimate incorporation by Henry VIII., and the extreme difference in the girth of the country, the language is considered, has gained less ground than could be expected. An Englishman travelling the public roads of the principality often meets with persons who speak English, and those whom he has occasion to address at this time have eighty volumes of the Welsh language; the gentry he may visit speak English, and those who call upon them probably use the same language in his hearing; and from these slight facts which come to his knowledge, he erroneously concludes that the English is the prevailing language of the country. It is only when a man has resided a long time in the interior, having intercourse with the common people, that he can form a true estimate of the extent of the Welsh language; and most persons will readily assent to the truth of the assertion, that the Welshman of the Cambro-Saxon Society男, but of tens of thousands, and even of some hundreds of thousands of the inhabitants of the principality.' (Cambro-Britons, vol. iii., p. 229.)

The Welsh language has not only become more firmly rooted in the Old World in recent times, but is also a bright and shining star in the New. While Dr. Macleod, in the preface to his 'Leabhar nan Cnoc,' exults in the hope that as Gaelic is destined to perish in the Highlands, it will survive beyond the Atlantic in the living languages of the numbers greater than ever spoke it in Europe, the Rev. T. Price, in his 'Hanes Cymru,' relates with similar exultation that he has received from America some numbers of a periodical, the 'Cyfaill yr Hen Wlad,' or 'Friend of the Old Country,' now for some time accessible, to which he attributes the prosperity of the Welsh language, and says that while the American volunteers for the 'delivery of lectures in the Welsh language on scientific and useful subjects,' and the translation of scientific treatises into Welsh.

Literature.—The quotation which was prefixed to a volume of 'The Cambro-Briton,' devoted to the cultivation of Welsh literature, is peculiarly happy: 'Nulli quidem mihi satis eruditii videntur quibus nostra ignota sunt.' The history of the literature of Wales is strikingly different from that of every other in Europe, and the apathy which has allowed the subject to remain in obscurity and neglect can hardly be explained.

The effect of this apathy has been that the most interesting points of the history of Welsh literature still remain to be subjected to investigation and criticism. The Welsh claim to be in possession of a body of poetical compositions the antecedents of which antedate the conquest of the thirteenth century. Till within the last half-century the proofs on which this assertion rests—the compositions for which this antiquity is claimed—remained buried in the libraries of colleges and of individuals, some so difficult of access, that literary men have not hesitated to employ the word 'evil' against the eighteenth century, who spent his life in researches into Celtic literature, had never been able to obtain a sight of some of the most interesting. This reproach was mostly, if not entirely, due to the apathy of the gentry of Wales, by the liberality of Owen Jones, a furrier in Thomas Street, who, at the expense, it is said, of more than a thousand pounds, collected and published, in 1801 and subsequent years, in three volumes, under the title of 'The History of the Literature of Wales,' the publication of Welsh literature for nearly nine hundred years, from about 500 to 1400. In this task Owen Jones was assisted by Edward Williams, better known by the name of Iolo Morganwg, or Edward of Glamorgan, and by Dr. Owen Price, the very name of whose undertaking was undertaken too soon. 'A number of manuscripts equal to what now remains,' says Owen, in the fourteenth volume of the 'Archæologia' of the Antiquarian Society, 'has perished through neglect within the last two hundred years, that is to say, within the period of the beginning of the sixteenth century.' By the publication of the 'Myrwyrian Archæology,' a vast mass of materials was preserved, and it did not comprise the whole of what Jones intended to publish—in the library of the Welsh school at London, no less than eight thousand manuscript books of various ages and sorts, were preserved, of which a thousand were intended for a continuation of the work. After the cessation of Jones's exertions, the old apathy returned, and continued till within the last two or three years. Dr. Owen exerted himself for several years to obtain support for the publication of the Bible in the Welsh, but died without accomplishing his purpose, which is now being carried into execution by Lady Charlotte Guest. At present the prospects of Welsh literature are more favourable than on any previous occasion. The annual journal issued by the poet Lewis Glyn Cothi, and has other publications in the press. Another association has recently been instituted, on the model of the Camden and similar societies, for the purpose of publishing manuscripts, whether in Welsh or other languages, connected with Wales; and these are to be accompanied with translations. It also announces a translation, by the Rev. J. Williams, of the 'Myrwyrian Archæology,' which had nothing English about it but its prefaces. In the latter portion of the plan of this society the second step is taken of the three which are requisite to bring the literature of Wales fairly before the world. The first is, the publication of its monuments, as indispensable materials for all that is to follow; the second, the rendering them accessible, to the opportunity of acquiring, in addition to the knowledge of the Welsh language as it now is, that of all its variations during a period of thirteen hundred years. The third will be, that of applying a judicial criticism to these materials; the fourth, the publication of the works of the antient authors, that of the introduction of rhyme and the origin of romantic fiction. At present the want of published materials in some cases and of adequate criticism upon them in others renders speculation on these subjects peculiarly vague and unsatisfactory.

The Welsh, it has been already stated, claim to be in
The authenticity of these poems having been impugned by Pinkerton, in his preface to Barbour, and by Laing, in a note to his 'Vindication of Myvrian,' it was maintained by Turner, that in his 'Vindication of the Genuine-ness of the Antient British Poems of Aneurin, Taliesin, Llywarch Hen, and Merdread,' first published separately in 1803, and since appended to the successive editions of his 'History of the Anglo-Saxons.' This dissertation has been spoken of in terms of the highest approbation, and is entirely free from the scathing criticisms which a more easy rapidity acquired the knowledge of our language, Mr. Sharon Turner, is the best writer that has ever appeared on the subject.

In this treatise Mr. Turner asserts the genuineness of the antient poems on both internal and external evidence. The oldest copy extant, he says, is an antient manuscript called 'The Black-Book of Carmarthenshire,' preserved in the library at Aberystwyth, which is presented by competent judges to be of the twelfth century; so that if forged at all, the poems must have been forged as far back as that period, while in fact they are alluded to as antient by writers of the centuries immediately following. It may be noted that a similar observation is made in the introduction to the Calibro Edition of the Welsh in which the genuineness is ascertained by the light in which it is presented by authentic evidence. Finally the language is a pretty well-adapted, often obscure, and sometimes unintelligible, and altogether different from that of compositions known to be of the twelfth century.

The most elaborate reply which has appeared to Mr. Turner's 'Vindication' is given in a criticism on it in the Edinburgh Review' for April, 1803. It is probable the objections of the critic appear to us to be scarcely deserving of notice. There is one however which he touches on lightly that seems of very great weight. Mr. Turner and others who maintain the authenticity of most of the antient Welsh poems do not maintain the authenticity of all; and if it be once admitted that some of the compositions which pass under the names of Aneurin and Taliesin are forged, the whole fabric which has been reared in their defence seems to rest on an insecure foundation.

It is true, that in his 'The Goddin,' bearing a very strong marks of authenticity, Aneurin was one of the northern Britons of Strathclyde, who have left to that part of the district they inhabited the name of Cumberland, in token that it was once in possession of a section of the Cymry. In this poem he laments the death of his comrade slain by the Saxons at the battle of Catterth, in consequence of having taken too freely of the mead before joining in combat. He commemorates many obscure chief-tons; it is the occasion of a song which is doubtless dictated by the freshness of grief. A portion of this poem has been translated by Gray; a version of the whole was inserted by the Rev. Edward Davies in his 'Mythology of the Druids,' and a translation of the whole works of Aneurin, 'The Goddin' and the 'Odes of the Months,' was published in 1829 by Mr. Prober.

The works of Taliesin, the contemporary and friend of Aneurin, are of a much more questionable description. There is a story of the adventures of Taliesin current among the Welsh Mathematicians, which has a strong similarity to many of its incidents to the productions of Eastern fiction. It is printed in Welsh in 'Myvrian Archaeology' and in Welsh, with an English translation, in the fifth volume of the 'Cambrian Quarterly Magazine.' According to this story, Gwion, the Welsh Cuckoo, was a slave, and his master, Merion, or Merioneth, a wacthful husbandman, in which he was preparing a concoction that was to bestow knowledge and genius on her son, incurred the vengeance of his mistress by involuntarily drinking the three breasts which contained these wonderful effects. Of course he became endowed with wisdom, and fled from the wrath of Kiridwen, who pursued him. He fled in the form of a hare, she pursued in that of a hound; when nearly overtaken, he turned to a fish, and she to an otter; by a stroke of his wand Taliesin was finally swallowed in the form of a grain of wheat by Kiridwen, in the form of a hen. After nine months she delivered of him again; and, unwilling directly to take his life, she lay in a leathern bag and cast him into the sea; after which he was found by Prince Elphin, the son of Gwyddno, at a weir on the sand between Dyvi and Aberystwyth. This strange story appears at first sight to be of the same character with those which were told of Virgil in the Cumbrian dialects, and of the 'Mabinogion' which exhibits a name from the wish to give it an air of authenticity in the eyes of ignorance. But this explanation is not sufficient. In the poems attributed to Taliesin continual allusions are found to this preposterous narrative; and it is thought that Taliesin by these allusions may be explaining the philosophy and metempsychosis; and he attributes to the effects of the caldron of Kiridwen the gift of prophecy, which he claims.

Mr. Peacock, in the novel of the 'Misfortunes of Elphin,' says, 'Where Taliesin picked up the story which he told of himself, why he told it, and what he meant by it, are questions not easily answered. Certain it is that he told this story to his contemporaries, and that none of these contradicted it. It may therefore be presumed they all believed it, and that the poet was perfectly honest in his desire to come down to it. It must be acknowledged however that the incidents of the narrative seem of a character likely to be invented in a century later than the sixth, and indeed some of the poems of Taliesin are of such which Mr. Turner seems to show the least inclination to defend. These poems exhibit also an introduction of the Greek and Latin metres into Welsh poetry, and even of scants of Latin, in the name of Wales in the celebrated lines prophetic of the fate of his countrymen, which have been quoted oftener than any other poems from Taliesin.

Ea Ner & volant
En bleddin & goddant
Ea sir & gaearn
Gwth gwlf Walla.*

'Their Lord they shall adore,
Their language they shall keep,
Their land they shall lose Except wild Wales.'

A belief in the authenticity of the other poems of Welsh antiquity would certainly be strengthened by the fact that it could be shown that the genuineness of those of Taliesin was not involved in theirs. There is still so much to be elucidated by the critical examination of these antient remains, that it cannot at present be ascertained whether this is the case.

The five Elegies and the 'Elegy on Old Age' of Prince of the Cumbrian Britons, with a literal translation by William Owen, were published in 1792. Llywarch Hen, like Aneurin, was one of the warriors of Strathclyde, and, like him, was driven to Wales by the successes of the Angles. The Elegies are ascribed to his memory, and have been ascribed to that of his the most celebrated of his countrymen, and are superior in interest. Profer, who remarks that 'their authenticity has been proved by Mr. Turner; and they are exceedingly curious. Some are in the form of a pastoral, others in the form of a lyric poem, others preserved in the notes to his 'Sir Thomas More,' with a universal strain as melancholy as it is rude. 'The Elegy on Old Age and the loss of his Sons,' and the lines 'Te Cuckoo in the Vale of Cyswy,' are particularly striking; but the latter poem is ascribed by some to a certain tribe of Llywarch, who lived towards the end of the fourteenth century; the former is shown to be Llywarch's by many circumstances mentioned in it. Some of the remaining poems in the 'Myvrian Archaeo-

Their language they shall keep,
Their land they shall lose Except wild Wales.'
The privileges of the bard form the most peculiar and interesting portion of those curious collections of Welsh laws, which are still extant from a very early period. The laws of Howell Dda, or Howell the Good, a king of South Wales, were compiled to his 'Suo Gwait' about the sixteenth century; but in a poem by Cynfeildil, of the date 1610, reference is made to still older enactments, to a concession of privileges to the men of Arvon by Run in the sixth century, and a similar one to the men of Powys by Cadwollan in the seventh. The last law known has been reprinted from its first appearance in Wotton's 'Leges Wallicae'; the last edition, in Welsh and English, is to be found in the 'Antient Laws and Institutes of Wales,' published in 1841, by Aneurin Owen, under the superintendence of Mr. C. Howell. But these two works, and all the general laws of Wales then collected, the bards were entitled to dues from marriages, to exemption from bearing arms, and to innumerable other privileges; and a bard was particularly favoured who knew the prophetic song of Taliesin.

In the 'Archaeologia,' p. 216, the principal heads under which ancient Welsh literature may be classified are—poetry, bardic institutions, laws, history, theology, ethics, proverbs, dramatic tales, and grammar; and that the work is more extensive, for it may be computed to fill about eight parts out of the ten of our old writings, omitting to take into account the heraldic collections altogether; but with respect to the quantity that is printed, such a proportion is as absurd as it is unfair. I have made a calculation so as to enable me to infer that I have perused upwards of 13,000 poetical pieces of various denominations for the purpose of collecting words, in the course of about eighteen years that I have been compiling the dictionary of the Welsh language.

The 'Triads' may be said to belong to most of the remaining classes, for they are by turns historical, ethical, legal, and theological. They are enumerations of a triad of persons, events, or things, occurring in one short sentence. This form of composition, originally invented in all likelihood to assist the memory merely, has been raised by the Welsh to a degree of elegance of which it hardly, at first sight, appears susceptible. The 'Triads' are indeed so happily put together without much attention to the date of their composition; the oldest are probably as old as anything in the language. Short as they are individually, the collection of the 'Myrwyen Archaeology' occupies ten pages of the 'Arber Collection.' The 'Wisdom of Cudog the Wise,' a collection of proverbs, said to be made by St. Cudog, who lived in the sixth century, from the then antient adages of the Britons, is much of the same style of composition as some of the 'Triads'; and indeed some of the great ones have the same shape.

In history the Welsh literature is not rich. Their first authentic antient historian is Caradoc of Llanearvan, who lived in the twelfth century, and wrote a history of Wales, an English translation of which was made about 1527, by Brapheyn Lloyd, published by Dr. Powell, in 1584, and has since been frequently reprinted, the last time at Shrewsbury in 1832. The original was printed in the second volume of the 'Myrwyen Archaeology.' It is a detached and choice chronicle of the Welsh.

The fictitious history translated by Geoffry of Monmouth had a very different fate from the dry records of his contemporary. His work, a 'History of Britain,' in nine books, in Latin, which, according to his own account, he translated from theump to the English by Walter Calenius, archdeacon of Oxford, who had collected them in Brittany, was written in the reign of Henry I, and appears to have been spread at once to the name of its hero, King Arthur, throughout Europe. It commences with the story of Brutus from Troy to Britain, and contains all the strange and wonderful stories respecting Arthur and Merlin which have become familiar to the readers of romance. There is a Welsh translation of this book, which goes by the name of the 'Chronicle of Tywilio,' and has been re-translated into English by the Rev. Peter Roberts, at the end of the manuscript of which is the singular note in Welsh: '11, Walter, archdeacon of Oxford, turned this book from Welsh into Latin, and in my old age I turned it the second time from Latin into Welsh.' It was long supposed that this was in this book the claim of Geoffrey of Monmouth, but it is now rather believed that his statement of being only the translator is correct, and that he really had a Welsh original before him. The arguments for this belief have been given by Mr. Ellis, in the introduction to his 'Life of Early British Antiquaries.' If there were Welsh originals, it becomes a question of considerable interest if they still exist; and the prevalent opinion now appears to be that they are to be found in the 'Mabinogion,' or Children's Tales, of which a long extract of the latest version is reprinted in the 'Red Book of Hergest,' preserved at Jesus College, Oxford. The tales in this collection are in prose; they comprise not only those of the court of King Arthur, but the Life of Taleisin, which is as well as any of its companions, a number of similar tales, and the story, thought of Hampton. Owen Pughe published several of the Mabinogion, in Welsh and English, in the 'Cambrian Register' and the 'Cambrian Quarterly Magazine,' and it has been suggested that there may exist a prose version of the original, and the whole, but could never obtain sufficient support. They are now being issued in numbers, under the superintendence of Lady Charlotte Guest, who declined availing herself of the translation of the whole, and prefers to wait for the publication of a separate translation by Mr. Tudor Parry, to be published in Welsh invention or tradition. The reasons in favour of this view have been ably summed up in an Essay on the Influence of Welsh Tradition upon European Literature, which obtained the prize proposed by the Abercromby University Society in October, 1848. Such a work, though not published, may be seen at the British Museum, to which a privately printed copy was presented by the author, Mr. J. D. Harding. Mr. Harding, in this Essay, and the Rev. T. Price, in his 'Bar of Cymru,' refer to the view, that the Welsh were first exercised in the Welsh versions of the stories of the Round Table which is contained by the original of Geoffry of Monmouth, or, like the Chronicle of Taliolo, taken from him; but in either case it now appears to be the prevalent opinion that the cycle of romance existed in Welsh invention or tradition. The reason for this view has been ably summed up in an Essay on the Influence of Welsh Tradition upon European Literature, which obtained the prize proposed by the Abercromby University Society in October, 1848. Such a work, though not published, may be seen at the British Museum, to which a privately printed copy was presented by the author, Mr. J. D. Harding. Mr. Harding, in this Essay, and the Rev. T. This poem is written in a phraseology so obscure to the modern reader, that the Rev. T. Price, who quotes it in his recently published ‘Hanes Cymru,’ thinks proper to add a version of it in modern Welsh. Dafydd (1160-1220) was a poet, and compiler with Gwalcmai, but of inferior talents. Forty of his pieces are printed in the ‘Mwyrrian Archaiology,’ of which the most interesting is his poem entitled ‘The Death-bed of Cynddelw,’ and his verses to Madoc, prince of Powys, the last of the bardic line of whom he was inspired, and is generally supposed to have discovered the emigration of Wales. A few of his rivals were illustrious for rank as well as genius:—Owain Cyveilioc (1160-97), the prince of Cyveilioc, a portion of Powys; and Hywel (1192-1250), one of the sons of Owain Godred, and therefore the brother of Madoc, who aspired to his father’s throne, and fell in the contest, the issue of which led to Madoc’s emigration from Wales. The most conspicuous production of Owain is the ode entitled ‘The Henlas Horn,’ or ‘The Long Blue Horn,’ which has been frequently translated since its first appearance in Evan’s ‘Dissertation on the Bards.’ The poems of Hywel are chiefly love-odes, of which the finest is one entitled ‘The Choice.’ One of their contemporaries, Llywonald (1170-1220), who was one of the poetical bards of severals of the princes, is commonly known by the singular appellation of ‘Friydd y Moch,’ or the ‘Poet of the Pigs,’ for what cause is not now ascertainable. One of his productions is an invocation, when undergoing the fiery ordeal, by which he was separated, to ascend heaven, if he possessed any knowledge of the fate of Madoc.

The names of the bards now become still more numerous, and the period in which they lived may be considered as the middle of the middle age, distinguished by—Einion, the son of Gwalcmai, the son of Meilly (1170-1220), of a family in which poetical genius seems to have been hereditary; Elidwr Sais (1160-1220), Philip Brydyyd (1200-1250), and Prydydd Bychan (1200-1250). Their poems are epics, and lay a claim to the princes and great men with whom they were connected. The next generation of bards must have been that which witnessed the conquest of Wales by the English. According to a tradition which has been made universally known by—The bard must have been by the example set by the invaders; but the modern story of the massacre of the bards appears to rest on no adequate authority. There is no memorial or tradition of it in the country which is said to have been its scene, and no allusion to it in the productions of the following. In the ‘Mwyrrian Archaiology’ there appears no greater falling off in the number of poetical productions than might naturally be expected as the result of a foreign conquest, of however mild a character, and the bardic system has continued to produce a bard who in nation and popularity surpassed all who preceded him.

Dafydd ap Gwilym has sometimes been called the Welsh Ovid, and sometimes the Welsh Petrarch, but is said by his patron to this office led to a contest of satire with less than to any other poet, whether of his own or other countries. His poems are of a character almost entirely new in the literature of Wales; the subjects of them are chiefly themes of love and social festivity, instead of valour and heroism. The exact dates of Dafydd’s birth and death are unknown, but he is supposed to have been born about 1340, and to have died about 1400; the incidents of his life are both interesting in themselves and curious from the light they throw on the manners of the time. He appears to have been the son of Gruffudd, lord of the town of Llandaff, when he took refuge in the house of the same Ivor, and to have been turned out of doors by his parents in consequence of impertinence to them. Here he became tutor and lover of Ivor’s daughter, whom, when the father found what was going on, he put in a nunnery at Anglesey, but not withdrawing his patronage from Dafydd, who composed many songs to the lady, and was about this time elected chief bard of Glamorgan, from which he is often called Dafydd Morganwy. His appointment to this office led to a contest of satire with Rhys Meigan, another bard, who reflected on the illegitimacy of Dafydd’s birth, but was answered in a poem of such pungency, that on hearing it recited he fell down and expired on the spot. The handsome person of Dafydd and his poetical talents made him at this time such a favourite with the ladies, that he grew sufficiently vain of himself by giving an assignation to twenty-four different mistresses, with all of whom he appointed an interview at the same spot, and, concealed behind the bushes, laughed at the meeting. They all, when they had discovered the trick, derided him, and the reflection on his own vanity and tenuity to make his appearance, and in a humorous verse desired her who had kissed him oftentimes to strike him first. The confusion and the mutual sneers of the women produced a battle, in the heat of which Dafydd escaped. He then put in another suit, but at length the woman who occupied the church thought otherwise, and Morvudd was soon after united, according to the rites of the Church, with Cynfrig Cynin, whom Dafydd christened ‘Bwa Bach,’ or the ‘Little Hunchback,’ and assaulted under that name with all the best was published to the assumed name of Maelog, in 1894. The poems of Dafydd are remarkable, among other things, for exhibiting the indications of an approach to a system of versification which was soon after carried to what may be called a point of perfection or system by the poet of the manuscript, Hael. The influence of Dafydd on the Welsh language, was as vital as that of the Church, and was not renewed until the time of Ivor Hael, wherein it was established in the form in which it remains to this day.

Our ‘system of versification,’ says Edward Williams, or Iolo Morganwg, in the ‘Cambrian Register,’ vol. i., p. 400, ‘the distribution of long and short syllables, the use of twenty-four different classes of the combination of verses, there was also another principle called consonancy, or the accordant sound of the same consonants from certain accented parts of the verse which casually embelished it. But this consonancy, being peculiarly musical in the Welsh language, was ascribed as a constituent part of verse at a congress held in the ninth century, at which presided Geraint, usually called Bard Glais, or the Blue Bard. The consonancy was afterwards modified and improved at different times, until about the end of the twelfth century, to suit the pronunciation of Ivor Hael, wherein it was established in the form in which it remains to this day.’
South, and which has been the means of leading modern writers into errors, whenever they have had occasion to speak of the two systems of poetry!

The Welsh name for this species of consanancy is Cynghanedd, and though more complicated, it has much analogy to the alliteration employed in Anglo-Saxon, Icelandic, and earlier English poetry, from which the first idea of it may have been borrowed. The Welsh name became popular at a student of English verse, composed in 1450, by a Welsh student at Oxford, to exhibit the advantages of the 'cross consanancy,' is printed in the second volume of the 'Cambrian Register.' A more recent example of it, given in the 'Cambrian Poems,' is more consonant with the English Language, and will perhaps convey a clearer notion of it than a lengthened description.

The lines are on Envy—:

A friend in Phobus' face he found,
That tender grew yet under ground,
To see his spleen disport not display,
Nor set the devil in his way.

But at the noon of night.

The introduction of Cynghanedd tended strongly to induce the poets of Wales to pay more attention to sound than sense, as may be conjectured from the specimen given, but it held its ground till in our own days, in 1819, Dr. Owen Pugh, by translating the 'Paradise Lost' into Welsh blank verse, with the twenty-first century's diction, was said to have led the way to a desirable reform.

The next distinguished poet after Dafydd ap Gwilym was Lewis Glym Cotti, who lived during the wars of the Roses. His works are less remarkable for their poetical than their historical merit. They contain two series of letters, one addressed to the original Welsh, with English notes, chiefly of explanatory historical matter, by the Gymromdonor, or Royal Cambrian Institution, in the year 1637, and occupy an octavo volume, which was edited by the Rev. John Jones, of Llanrwst, in 1837, and published, without much elegance in the 'Cambrian Register,' among the first of the Welsh poets. He eminently excelled in that talent which we call humour, and was equally master of the pathetic and the sublime.

The same writer states that his 'Elegy on the Death of Mrs. Middleton' is equal or superior to 'the two most beautiful compositions in the English language on the same subject, the 'Monody' on the death of his lady, by Lord Lyttelton, and that 'to the Memory of a Young Lady,' by Mr. Shaw. The latter, he says, was the best poem ever written in Welsh, in octavo volumes, at Wrexham, in 1625, under the title of 'Eos Ceirig,' or 'The Nightingale of Ceirig.'

The most distinguished bards of the eighteenth century were Goronwy Owen, Evan Evans, and Edward Williams. Goronwy Owen. These documents contain the names of the greatest poets that appeared among the Welsh. He was the son of a peasant in Anglesey, and was indebted for his education to Mr. Lewis Morris, a distinguished antiquary, who had him brought up for the church. He married in Oswestry, where he was curate, and says in one of his letters, 'My wife speaks very little Welsh, yet she understands some; so that I fear that if I go not to Wales, my boys will be Saxons, for by the life of me I cannot teach the eldest one word of Welsh.' He was curate to Dr. Douglas, and composed in the third person, in one of his letters, 'who defended the poet Milton against the insidious defamations of Lauder. He it is may he, it is sufficiently severe and hard towards me. I hold some little land of him appertaining to the school, and though it was set too high before, yet he has sent down this year orders to raise the rent, lest a poor wretched curate should gain anything in his service, or obtain too good a bargain at his hand.' This and similar treatment at last induced Owen to petition the Gymromdonor Society, in 1757, for assistance towards paying his passage for America, where he settled at Williamsburg in Virginia; and after the year 1767 nothing further was heard of him. About the year 1798,' says Owen Pugh, in the 'Cambrian Biography,' 'some persons in England attempted to obtain information if he were alive or dead, and with that view sent a letter over to his son. Him they found perfectly Americanized: before any answer was sent, he must first know who would pay him for his trouble.' The principal poems of Goronwy Owen were printed in the first volumes of a book called 'Dawnach Ffzlaidd,' printed at London in 1763. The book has a curious English preface by the printer, who states that it was 'put into his hands by the editor, Hugh Jones,' who 'owned himself incapable of writing an English preface to it, and therefore desired me to do that office for him.' The editor, he adds, 'being an itinerant bard in the manner of the antients, hath given me leave to tell his readers that he pretends to neither learning nor languages; he despises them all except his own, as the chief Greek poets did, calling other languages barbarous. He considers that no country or French nations have anything that may properly be called poetry; such is man's partiality towards his own country and people.'

The Rev. Evan Evans was born in Cardiganshire in 1731. He also was patronized by Mr. Lewis Morris, and educated for the church, but rose to no higher station than that of a curate, and at his death, in 1788, was reported and believed to have perished from want on a mountain. He afterwards published two volumes of Welsh sermons, 'Ddibartado Bards,' 'Specimens of Ancient Welsh Poetry,' and a poem entitled 'A Love of our Country.' His two works were more come more appreciated since his death than before. Jones, the historian of Brecon, says, in a letter, written in 1797, 'I did not think Evan Prydwyd Hir' (the bardic name of Evans) 'the poet he was. I knew him well, yet I suppose the poet who expelled the accent before it became acquainted with him.'

Edward Williams, known by the Bardic name of Tolo Morganwg, was a poet of merit both in Welsh and English. He was born in the parish of Llanearvan in Glamorgan, about the year 1717, and was of a religious turn of mind, his father being a curate of Gower; but he was given to the study of literature, and published, in 1704, present perhaps the most curious list of subscribers that ever was attached to any publication. It begins with the name of the Prince of Wales; it contains those of Mrs. Barbauld, of Dr. Johnson, of Lord Byron, of Dr. Bowles, of the Archdeacon of Cardiganshire, of General Croom, of the Rev. William Jones, Miss Hannah More, Lord Orford, Thomas Payne, Samuel Rogers, Miss Anna Seward, John Horne Tooke, Wilberforce, and General Washington. He afterwards published, in 1716, two volumes of prose, called 'Llancrwn,' and 'Cyfrinach Beirdd Prydain,' the latter contains the complete works, as the name signifies, of the bardic poets of Wales, with a biographical introduction by the bardic poet, or 'Salmag yr Eglwys yr yr Anialwch.'

Williams worked during his life at his trade as a stonemason. He lived for some time in London, and was anxious to emigrate to America, but returned to Wales, and lived and died there. He was intimate with the wealthiest and most influential persons in his country; he was one of the editors of the 'Mvyrrian Archeology,' and he was, in 1793, about to publish a collection of documents illustrative of Welsh history, but seems to have been prevented from want of sufficient support. The work was never published. It seems to have been prepared by the Welsh Manuscript Society, under the editorship of his son, Mr. Taliesin Williams, who published, in 1789, his father's 'Cyfrinach Beirdd Ynys Prydain,' or 'Secret of the Burds of the Isle of Britain.' Tolo died at Flemingstone in Glamorganshire, on the 17th of December, 1805, and Southey says, in his Life of Cowper, 'It grieves me to think what curious knowledge, and how much of it, has probably perished with poor old Edward Williams.' From some letters by him, which were printed during his lifetime, it appears that he was intimate with the bardic poets of the three countries, and that it seems that he had written his autobiography, in which he had introduced an account of Welsh literature during his own time, as well as his opinions of Welsh literature in general. This work would probably be of value, as his opinions on these subjects appear to have been formed.

The epithet which has been given to a writer contemporary with Edward Williams, 'the Cambrian Shakspere,' would give a stranger an idea that such a man had been born, and a little child beginning to read, 'This is the house that Jack built.' It is much easier to compare this to the writings of
Shakspere than anything that was ever written by Twm or Nat, whose interludes consist of nothing but the lowest and most indignt buttsynt in the human mind. "Twm or Nat," or Tom of the Valley, was the Bardic name of Thomas Edwards, who was born in the year 1738, in Denbighshire, and died, we believe, about 1802, at the age of sixty-four years. He was introduced to the Welsh bards by his father, who was a native of Anglesey. He was a person of much more than ordinary merit, and is, to this day, regarded as one of the most estimable of the bards who have ever lived in the country. His interludes, "Enterlude," as he calls them in Welsh, resemble, if we may judge by their titles, which are given by a correspondent in the "Gwladgarwr" (vol. vi., p. 144), the Mysteries which preceded the establishment of the Church of England in the most civilised parts of Europe. One of his dialogues between a Protestant and a Dissenter; another between Pleasure and Misery. The dates of these are 1763 and 1767: he afterwards advanced nearer to the regular drama, for, in 1812, we have the "Ysori Richard Waddington," or a figure of an Archbishop of Canterbury, with an original title, "The History of Whitlington," third Lord Mayor of London.

The Cambrian Shakspere deserved his title much less than Dr. Owen Pughe would that of the Cambrian Milton. Dr. Pughe was equally eminent as an antiquary, a lexicographer, and a poet. His principal work of the latter description is his "Coll Gwyna," a translation of the "Paradise Lost," which has already been mentioned as distinguishing itself for throwing off the yoke of "Cymhangelid." He also translated the "Dafydd Ddu," or the principal bard, "Nugadarn," or "Hu Gadarn," or "Hu the Mighty," commemorative of the exploits of the prince of the Gwynedd, famous in tradition, who conducted their migration from "Deforba," or "Summons," to the county of Merionethshire, in 1759, and died in 1835, in his native county, to which he had returned after a long residence in London.

Mr. Edward Jones, who was appointed bard to the Principality of Wales in 1783, was also a native of Merionethshire, and died in London in 1824. His "Relics of the Welch Bards" are valuable from the specimens they contain both of the poetry and the music of Wales, but the English translations which he gives of the Welch passages are by far the most judicious and correct of any. Mr. Jones, who was the author of "Welsh Melodies," with poetry by Mrs. Hemans, has superseded much of the utility of Jones's work for the musician; but we understand that a new edition of the "Relics" has either appeared, or is about to appear under the superintendence of Mr. Pentrechwyth.

The Welsh Paranaus of the nineteenth century is crowded with candidates for fame, many of whom have received the highest praises from Cambrian critics. It may be observed of some of the best producing pieces, many of them on the casual occurrences of the day or on subjects dictated by societies. Our limits will not allow us to give more than very brief notices of the most copious. As usual North Wales is the most active and most fertile in the production of the national language. In Denbighshire and the adjoining parts the most prolific county is Denbigh, the bard of Edward Jones, (by his bardic name Dewi Wyn), was born in Caernarvonshire in 1784, and died in 1841, after a life spent in rural pursuits. His poetical works were collected in one volume, and published at Chester in 1841, under the title of "Blodau Arfon," or "Flowers of Arvon." The Rev. William Williams (Gwilym Caedelyn), of Caernarvon, is the author of an interesting volume of poetry, entitled "Grawn Awen," or the "Treasures of the Muse," and Mr. David Thomas (Dafydd Ddu Eryn), of Caernarvon, who was drowned in 1822, had produced some poems, the merit of which has been lost occasion of their publication. A Life of the author prefixed. Mr. David Richards (Dafydd Idris), of Denbigh, is the author of four or five volumes of poems, which enjoy the reputation of being some of the best in the language. The Rev. John Richards, of Llanerchymedd in Anglesey, and the founder of Sunday-schools in that island, who died in 1832, in his seventy-sixth year, was also a poet. Mr. Evan Jones (Gwennfrod), of Holywell in Flintshire, who went to America in 1832, and died in Alabama in 1834, in his twenty-fourth year, had translated Thomson's "Seasons" and "Gardens and Villas," and published, in 1831, a small but useful volume, entitled "Cymraeg Awon y Clym yr Alban, or the Beauties of Welsh Poetry." In South Wales the principal seat of the "Aw'en" is Merthyr Tydvil. Tilais Williams, the son of Iolo Morganw, has followed the example, instead of the advice of his father, who, like Sir Walter Scott, was anxious that none of his sons should be poets. He is now a schoolmaster at Merthyr, which being a busy town, gave him much more practice in the business. John Thomas, who is said by his admirers to be the best minstrel in South Wales, and of a third, in the inkeeper Edward Williams (Iolo Mywny), Two of the most distinguished minstrels in South Wales are the Rev. Daniel Evans, of Jesus College, who assumes the name of Daniel Ddu o Gerdrigion, and the Rev. John Jones, of Christ Church, who takes that of Tegid. A collection of poems by the former was published at Cardiff, and the latter at Oxford. The title of the "The Poet's Vineyard": the productions of Tegid must be sought for in numerous periodicals; they are noted for grace and neatness of expression. There is one Welsh poet of note in London, the Rev. James Hughes, of St. John's, minister of Jewin Crescent Chapel; who is also the author of a popular exposition of the Old and New Testaments.

The prose literature of Wales in modern times may be said to commence with the translation of the Bible, the work of which is carried on by societies. It was enacted by Parliament that the "Bible, Testament, and Common Prayer" should be translated into the British or Welsh tongue; should be viewed, perused, and allowed by the bishops of St. Asaph, Bangor, and St. David. The translations were published by the London, Edinburgh, and Dublin, of Dr. Morgan, and used in the churches by the Ist of March, in the year 1786, under a penalty, in case of failure, of forty pounds, to be levied on each of the above bishops. In 1857, one year after the time fixed by the Act to profess the language, the works were again printed, more than twenty years elapsed before there was a version of the Old. The reasons are probably those conjured by Llewelyn, that the time allowed was too short, the persons that could be employed upon it too few, the penalty allowed the public too little, the expense of the work too great, and that the body of men who have had no funds assigned them to carry on the work, to go to the expense of procuring a translation, which must have cost each of them much more than forty pounds. In fact the whole affair seems to have dropped to the ground, and nothing of any consequence has been done for the Welsh language since 1788, was executed by Dr. William Morgan, vicar of Llan Rhaiadr, in Denbighshire, not in consequence of the Act of Parliament, but because he felt the necessity of the work. Morgan was promoted, in 1857, to the see of Llandaff, is translated, says Llewelyn, to St. Asaph, and in 1801, to a better place." His successor at St. Asaph, Dr. Parry, published, in 1820, a revised edition of this Bible, with such considerable alterations that it might almost be considered a new translation. Though the New Testament continues in use to the present day. Owen Pughe mentioned, in 1802, that nineteen editions of the Bible, consisting of upwards of a hundred and thirty thousand copies, had circulated in Wales. Llewelyn published, in 1788, "A Gentleman's History," a work which appears to have no relations and editions of the Bible," which is very amusingly written.

The early editions of the Welsh Bible were printed in London, and the introduction of typography into the principality was exceedingly slow. Cotton, in the "Typographical Gazetteer," states that the earliest information he possesses on the subject is from one of the Martin Prebyslute tract in Queen Elizabeth's reign, in which mention is made of the "knack" that well the printer, who printed the tract," have been the first to be printed in Wales. W. Owen Pughe says nothing more has ever been discovered of this printer or his books. In the "Gentleman's Magazine" for August, 1821, it was observed, by a correspondent, that "from the invention of printing downwards to the present day, the circumstances attending the diffusion of Welsh literature, that there was not a printing-press in the principality until the year 1734, or thereabouts, when a temporary set up by Mr. Lewis Morris, of Bod-Edeyrn, in Anglesey. Of the printers, none of which is known to be on the books of Mr. Thomas Parry, the most important add is, still in being at Treveirg, near Llanmartan."

Affairs seem to have continued in this apathetic state till the close of the eighteenth century, when two principal engines were set in motion which have since changed the whole face of literary affairs in the principality—the one the establishment of periodicals, and the other the establishment of societies. The first Welsh periodical appeared about the year 1770; its title was "Eurfrawga Cymraeg," or "The Welch Treasure," it was edited by the
Rev. Peter Williams, of Caermarthan, and Evan Thomas, a Welsh poet from Montgomeryshire, were the first of these to appreciate the list of eight periodicals then in existence given in the preface to the second volume of the 'Transactions of the Cambro-Briton' in 1824, and the statement in a number of the 'Cambrian Quarterly Magazine' for 1851, that at that time not less than fourteen periodicals in the Welsh language issued monthly from the press.

The principal now or lately in being are—1, the 'Seren Gomer,' or 'Star of Gomer,' which, first commenced as a newspaper, has since 1810 appeared at Caermarthan in the form of a periodical, containing biographies, reviews of books, &c., a tolerably complete view of the passing literature of Wales, but is perhaps on the whole rather a religious than a literary periodical. It was founded by the Rev. Joseph Harris of Tenby, a popular writer and author of several works both in English and Welsh, who died in 1825, and whose son, John Harris (Jeuan Glyn Tawr), who died in 1824, in his twenty-first year, was a poet of merit. 2, 'Y Gwaigddwr,' or 'The Patriot,' published at Aberystwyth since 1833 to 1841, was of a more exclusively literary character than the 'Seren Gomer.' Its first editor, the Rev. Evan Evans (Jeuan Glyn Gereiniog), a native of Trefriw, near Llanrwst, is a distinguished bard, author of the 'Seraph,' and officiates as a member of the local body over the poetical part of their national library. 3, the 'Clychgrawn,' or Welsh 'Penny Magazine,' the publication of which was commenced in January, 1834, and discontinued in June, 1835, consisted principally of translations from the works of the Useful Knowledge Society or of literary and miscellaneous papers, and was published under the Society's superintendence. It was edited by the Rev. John Blackwell, of Mold in Flintshire, and late rector of Menneihad in Cardigan, a distinguished member of the society, and was intended partly to the prevalent taste of the Welsh public for secular publications. 4, 'Y Drysorya,' or 'The Treasury,' edited by John Parry, under the superintendence of a committee of the Calvinist body, published since 1830 until 1833, was intended to be distributed mediately to the poor, but it did not attract many readers. 5, 'Yr Aithr,' or 'The Instructor,' edited by H. Gwamein, and published at Llanidloes since 1836, and 6, 'Y Dwyygiw,' or 'The Reformer,' conducted by a committee of ministers of the Independents, commenced at Llanelly in the same year and lives there to this day. 7, 'Yr Haul,' or 'The Sun,' and 'Y Gwybeddwyd,' or 'The Sentinel,' and others of inferior note. All of the existing periodicals give a summary of the occurrences of the day, and we believe that all are of the liberal or reforming side in politics, and none of them have any object but to be read by their readers, or to answer the purposes for which they are published. These periodicals now compose almost the whole of the current literature of Wales. As in poetry scarcely a single Welsh author has been found to venture beyond the limits of a short lyric piece, it seems as if the confined limits of the metrical form are too much apathy sufficient for the ambition of their writers in prose.

This is perhaps the most appropriate place to mention that some of the most valuable information in print with regard to the literature of Wales is comprised in three periodicals in the English language, devoted exclusively to Welsh subjects. The earliest of these, the 'Cambrian Register,' extends to three volumes, the first of which was published in 1796, the second in 1798, and the third in 1800. It has been the periodical publication more rich in original information of interest. The letters of distinguished Welsh antiquaries, which form a portion of its contents, are particularly entertaining; and a history of Welsh poetry, which appears in the general, is a respect to be admired. The book is entitled 'Cambrian Register,' but the design as yet remains unaccomplished. It is probably reserved for the achievement of the 'Society for the Publication of Antient Welsh Manuscripts,' which was founded at Abergevenny in 1857, and is announced in its report for 1858. The following pullicate 'The Cambrian Register' a great deal of the valuable work of its recent authors than will be found elsewhere. Dr. Owen Pugh was one of its principal contributors. 'The Cambro-Briton and General Celtic Repository,' also in three volumes, published at Carmarthen in 1818-22, has been very valuable, and indispensable in the library of every one who wishes to become acquainted with the history, the antiquities, and the literature of Wales. The 'Cambrian Quarterly Magazine,' in five volumes, published from 1823 to 1833, is unfavourably distinguished from its predecessors by the admission of articles of mere light reading; but some of them are of an extremely valuable and interesting character, and the attempts to trace the literature of ancient Britain,' by the Rev. Thomas Price, inserted under the signature of Carnhuanwae, is a signal ornament to the work. The eleven volumes of these periodicals should find a place in every public library in England, or even in any private collection of modish taste, where the literature of ancient Britain and the modern literature of a considerable portion of it, are not objects of absolute indifference. They comprise almost all the information on the subject at present accessible to the English reader—deficient as it is in fact, in the attention, however scattered over many volumes; but the English can scarcely complain of the deficiency of a general and satisfactory survey of the literature of Wales, while as yet they have nothing of a similar kind for their own country.

The societies of Wales, though not very successful at first, have been in the long run most effectual in reviving the taste for its literature and the study of it. The earliest of them seems to have been the Cambro-Briton (Associates) or Metropolitan Cambro-Briton, which was originally established in London in 1751. Its immediate purpose was to cultivate the language and literature of Wales, and its members were also to contribute their endeavours towards the instruction of the ignorant and the relief of the distress of the poor. It contained among its members a great number of books and MSS. relating to Wales, which were afterwards deposited in the library of the Welsh school in Gray's-Inn Lane, but did little else in a literary point of view, and after an existence of thirty years appears to have gradually expired. It was succeeded by the Cambro-Briton Society, founded by the Gwyneddigion, or Society of the Inhabitants of Gwynedd, or North Wales, which was established in London in 1771, by that indefatigable patriot Owen Jones. It has been a land of publication of various literary works connected with the principal, but its chief aim is to keep alive the attachment to the national music and poetry. With this view it has revived the ancient congreses of the bards, and conducted the famous 'Mynwent' of the society. It offers a national instrument, the harp, and the writers of the best Welsh poems on subjects selected annually for the occasion. The London Cymrameiddigion Society, founded in 1795, was intended to place the natives of Wales in communication with the English, and, in respect of the opportunities of acquiring useful knowledge; and for this purpose its meetings once a month were to be devoted to the delivery of lectures in the Welsh language on scientific and useful subjects. But the object has been already mentioned, however that one of the last public acts of this society has been to reward the Rev. J. Bray for his 'Essay on the Means of Promoting the Literature of Wales,' in which he recommends the establishment of a society for preserving the ancient system of language among the Welsh. The second 'Cymraddoriaid' Society was formed in 1823, at a meeting held at the Freemaasons' Tavern, and has similar objects with the first. It commenced the publication of its 'Transactions' in 1822, and some parts have since been issued, but they have not as yet reached to the extent of two volumes octavo. The library of the Cambro-Briton contained the manuscripts collected by Owen Jones for the continuation of the 'Mwynyn Archeology,' and has been the following publication of its recent contributions to a library of Welsh history, 'The Laber Landavensia,' or the Antient Register of the Cathedral Church of Llandaff, in Latin and English, under the editorship of the Rev. W. J. Rees, and the 'Heraldic Observations of Wales,' the 'Lives of the Welsh Eirioms,' and other valuable publications that have recently been made in London, chiefly, we believe, by Mr. Hugh Williams, to found a Cambrian Library, or collection of books in Welsh or relating to Wales—a very desirable object, and one that might be effected
at a comparatively small expense, if taken in hand, as it now appears to be, with judgment as well as zeal. It is probable however that in a short time a collection of Welsh literature much superior to any that has hitherto been seen will be formed at the British Museum. The Cymrnodorion Society of the University of Cambridge has also, under the presidency of Dr. Dyce (July, 1843) come to a resolution to present to that establishment their separate collections, with the view of rendering them more generally accessible to the public. The Welsh manuscripts at the Museum were already of considerable interest, and this additional collection will decide at the head of all the kind: in the printed book department the accession will probably have a similar effect.

The expert opinion of the Gwyneddigion at the Aberystwyth Literary and Scientific Institution, who have been inquiring into the Welsh language and literature, is that the collection is a very valuable one, and that the addition will probably have a similar effect. The Welsh manuscripts at the Museum were already of considerable interest, and this additional collection will decide at the head of all the kind: in the printed book department the accession will probably have a similar effect.

As those and but the king was also frequently seen in Suabia. Some of the tents were divided by partitions, and the hornier was produced by the secretion from the walls of the cysts. These horns mainly grow on the forehead or some part of the scalp. They are generally small, but instances are on record of their being eight or nine inches long and two or three in circumference.

In ordinary cases the cyst has only one cavity, but it does not infrequently happen that there are partitions in it, dividing its interior into cells of different sizes. The contents of the body of the cysts vary, some are filled with a thin, fetid, brown fluid, mixed with flakes of the fibrinous parts of the blood; some contain serum; some a matter of gelatinous consistence; some a calcareous matter; some a black fluid; and some a mixture of a mucusy and mucous matter. These containing hair are mostly found in the neighbourhood of the eyebrows or eyelids.

On dissecting these tumours, some part of their surface is found firmly adhering to the skin, while other parts are covered by a clear and thin membrane, always more or less embedded in cellular membrane. In some cases these cysts are congenital, and persons who have them are frequently troubled with a great number in various parts of their body.

In the treatment of them two modes may be had recourse to; by the one by puncture, the other by removal. When the cyst is small and presents a small black point on its centre, it may be opened and the contents pressed out, when it will sometimes get well. But it frequently happens that the pus will not be discharged by the incision, and that the inflammatory action is the result, so that painful suppuration occurs, and life is put in danger, and sometimes a bleeding fungus has protruded itself through the aperture. The suppurated matter is then removed with the knife, where their situation will permit of it. When this is done, the cyst may either be dissected out entire, or it may be cut into two halves, and each half may be dissected out separately. In both cases great care should be taken to remove the whole of the cyst.

WENCESLAUS, or WENZEL, emperor, or more correctly king, of Germany, the eldest son of the emperor Charles IV., of the house of Luxembourg, was born in 1361. Charles intended to intrust the education of Wenceslaus to his personal friend Petrach, but the post declined the honour, and the young prince was instructed by other teachers. The system of education, which was planned by the emperor himself, was bad; and the consequences were that Wenceslaus became unfit for the high post for which he was intended. At the age of twelve, he was crowned king of Bohemia; at sixteen, he was invested with the margraviate of Brandenburg; and at sixteen, he was chosen king of the Romans. From the accession of Rudolph I., in 1273, no Roman king had been chosen or crowned without the power of the investiture in the order. The latter is the most important of the great possessions, and in the hands of the emperor, for the king of Bohemia had no power to confer it. The opposition to this was, that the election of the Roman emperor was not a matter of descent, but of election by the barons, and that the Romans were free to elect whatever they pleased. The result was that the Roman emperor was at the mercy of the barons, and that he had no power to impose his will on them. The barons were, therefore, determined to make the election of the Roman emperor a matter of descent, and that the Romans were free to elect whatever they pleased. The result was that the Roman emperor was at the mercy of the barons, and that he had no power to impose his will on them. The barons were, therefore, determined to make the election of the Roman emperor a matter of descent, and that the Romans were free to elect whatever they pleased. The wealth of Charles, who is said to have given one hundred thousand gold guilders to each of them, besides estates and other advantages, and thus Wenceslaus was chosen king at Frankfort in 1376.

Wenceslaus succeeded his father in 1378. On his deathbed Charles said to his friends and followers that the lands for which they had made the king of kings. Be peaceful, and never try to obtain by war what thou canst obtain by peace. Do honour to everybody who deserts it; be a friend of the pope, the priests, and the Germans: thus you will reign in peace. The latter was the advice of Charles, but Wenceslaus did not follow them. The dominions of Wenceslaus were, the kingdom of Bohemia, with the Free State of Silia, the Upper Palatinate, and a great number of small fiefs over all Germany. His brother Siegmund was made margrave of Brandenburg and Bavaria, and Wenceslaus had ceded to him, and became afterwards king of Hungary; his brother John held WurtzBURG as a free city of Bohemia; his cousin, John of Luxemburg, was margrave of Moravia, which was a fief of Bohemia; the duchies of Luxemburg, Limpurg, and Brabant, which were possessed by an uncle of Wenceslaus, whose name was likewise Wenceslaus, were to return to him after the death of his uncle. The wife of Wenceslaus, Jane of Bavaria, was the sole heiress of her uncle, William of Bavaria, in his counties of Holland, Zell, and Hainault. The Netherlands under one head, and the foundation of a powerful state in the north-eastern part of Germany, two plans, the separate realization of which was afterwards possible with the help of the princes of Prussia—these two plans, and still more the change of Germany into an hereditary monarchy of the house of Luxemburg, might have been carried into effect by Wenceslaus, if he had acted with prudence, forbearance, and firmness.

The state of the empire was this:—After the death of Pope Gregory XI., at Avignon, in 1378, the Roman cardinals chose Urban VI., who was to reside in Rome. The French cardinals however chose Clement VII., who maintained himself in Rome. The dispute was at length settled by the election of Urban VI., and took up his residence at Avignon. Wenceslaus recognised Urban VI. as pope, and in return received the papal recognition of his election to the imperial throne, which he had not yet obtained. This policy, however, was disapproved of by Charles V., and, after him, Charles VI., from which however he disentangled himself by an alliance with King Richard II. of England, in 1381, who married the emperor's sister, Anne, and who likewise recognised Urban VI. As a successor of Clement VII., which was at the same time requested to be by the pope, the emperor was unable to quell them, and he only quieted Clement VII.'s adherents among the princes of the empire by granting to them several important privileges. To these was added the right of the imperial rights over the free cities of Suabia (for a large sum of money); but these cities, fearing that they would lose their freedom under Leopold, concluded an alliance to which a great number of towns and free cities on the Rhine adhered, and they defended themselves against the duke. Some other princes of Southern Germany also tried to obtain imperial rights, and then gradually the sovereignty over other towns and free cities, and for that purpose they concluded a union, which was headed by Eberhard, count of Wurtzburg and Leiden, duke of Austria, who had very extensive possessions in Suabia. The consequence was a dreadful civil war between the princes and the citizens, whose party was strengthened by the towns and cities of Switzerland, which was then a prince of Germany, and which had been invaded by the Jusus of Austria. The war was terminated by the battle of Sempach (9th of July, 1386), where Duke Leopold of Austria was slain, with 860 counts and knights; but in Suabia the citizens were routed at the battle of Désingen (24th of August, 1388) and in several other engagements, in which the citizens were on the general side, but whose measures were partial, and had no effect. In order to please the victorious princes, he cancelled the heavy debts which they had contracted by borrowing money from the Jews, and many other instances in Germany, England, and France: 2000 Jews were killed by the mob in Prague. For some time the emperor, who seldom left Prague, succeeded in maintaining peace in Bohemia and other parts of his own dominions but he abandoned himself to
Lamarck arranges Scalaria between Vermeius and Delphinia.

Cuvier observes that the Scalaria, which he places between Turritella and Cyclostoma, have, like the Turritella, the spire elongated into a point; and, like the Delphinia, the mouth completely formed by the last whorl; this mouth is moreover surrounded by a bourrelet, which the animal repeats at intervals, so as to form a succession of step-like elevations. He describes the animal as having the tentacles and the penis long and slender.

M. de Blainville gives Scalaria its position between Proteo and Vermeius, but wherever the animal repeats at intervals, so as to form a succession of step-like elevations. He describes the animal as having the tentacles and the penis long and slender.

The state of the Church was still deplorable: Boniface IX., the successor of Urban VI., was pope at Rome, and Benedict XIII., the successor of Clement VII., was pope at Avignon. The doctrines of Wickliff had found their way into Bohemia, where they were propagated by Huss; and, on the other hand, Huss was drowned at Moldau, after Wenceslaus had tortured him with his own hand (1389). He showed himself faithless to his own brothers, and Jobst of Moravia, who surprised the emperor and put him in a prison, in order to obtain justice from him. Jobst restored his captive to liberty by the summons of the other princes, who would not allow the head of the empire to be kept a prisoner, though this head was unworthy of his exalted rank. As Wenceslaus resided at Prague, and seldom appeared in public, his brother Siegmund, who was appointed vicar-general, was considered the general of the Roman empire, and kept for himself nothing but the imperial name.

Mr. G. B. Sowerby, jun., has made out at least eighty recent species, the numbers being, generally speaking, pretty nearly equally divided between the true and the false Wentletraps; the whole of these will be figured in a forthcoming number of his new and accurate work, three parts of which have already appeared under the title of Thesaurus Conchyliorum.

Habits. Locality. &c.—Species of this genus, which is marine, have been found at depths ranging from seven to thirteen fathoms in sandy mud. The True Wentletraps are found in the seas of warm climates; some of the false (Scalaria communis, for example) occur in the European seas and upon our own coasts.

Examples, Scalaria communis (Turbo clathrus, Linn.).

Description.—Shell turreted, imperforate, white or pale fuscous; the ribs rather thick, smooth, and suboblique. There is a variety of this species with the shell rather longer, rose-violaceous, and with purple-spotted ribs. Length of the common variety about 16 lines, of the rose-violaceous variety 17 lines and a half. (Lam.)

Scalaria pretiosa (Turbo scalaris, Linn.; Actia scalaris, Leach).

Description.—Shell conic, umbilicated, contorted into a loose spire, pale yellow, with white ribs, the whorls dis-jointed and smooth, the last ventricose.

Locality.—East Indian seas; China.

This shell was the one selected after by collectors, who was known among the French as the Scala, La vraie Scala, and Le véritable Escalier; among the Germans as the Rechte Wendeltreppe, among the Dutch as the Oprechte Wendeltrap; among the Belgians as the Wendeltreppe, and to the English as the Wendeltrap, Wendeltrap, and Royal Staircase.

The specific name given to it by Lamarck was at one time well deserved on account of its rarity and the great price which a fine specimen would bring in the market, especially when it exceeded two inches in height: such a specimen has been sold in former days for 2400 livres, or 100 lories! But those times are gone by; the shell is no longer rare, and good specimens only fetch shillings where they once brought pounds. The very fine example however still commands a considerable sum. That in Mr. Bullock's museum, supposed to be the largest known, brought 27l. at his sale, and was, in 1815, estimated at double that value.

Fossil Scalaria.

The number of fossil species (tertiary) recorded by M. Deshayes, in his Tables, is twenty-two; we have above noticed those recorded by him as recent and fossil (tertiary). Mr. Lea has described among others the genus Scalaria, and quenquefaæcata, from the Clifton Beds (tertiary of Alabama). Mr. Pitton figures one, Scalaria pulchra, from the strata below the chalk (Blackdown).

WENTWORTH, THOMAS. [STAFFORD.] 

WOEBLY, [Herefordshire.]

WERECH. [WERCHEL.]

WEREJA. [Moscow.]

WERN, OLAF. [VERELIN, OLAF.]

WERNER, ANNA MARIA COTTWALD, was born on the 25th of September, 1750, at Welslau on the Queis, in Upper Lusatia. His father was superintendent of a foundry at that place. He gave his son minerals as playthings, and young Werner thus became acquainted, says Cuvier, with the names of their various shapes and the letters of the alphabet. He received his early education at the school of the orphan asylum at Bunzlau in Silesia, but was afterwards placed at the celebrated school of mines at Freiberg in Saxony. He soon formed the resolution of entering in the mining establishment at that place; and as the regulations required a licentiate's degree in law before admission, he studied jurisprudence for three years at the university of Leipzig, but at the same time continued to cultivate a knowledge of mineralogy. At that university, Werner published three memoirs of a geological character, in a year, four years of age, a treatise on the external characters of minerals, in which he proposed a methodical and precise language to describe the sensible qualities of mineral substances. By this work, consisting of a few leaves, Werner, says Cuvier, rendered a service to mineralogy analogous to that which Linnaeus had rendered to botanical science by the terminology made use of in his Philosophia Botanica, and effected a revolution in the science of mineralogy. He here expressed his ideas on the deficiencies existing in mineralogical science, and on the means of removing them. He observed that the external characters of minerals had been neglected in their description; and at the same time he showed that these characters were not to be applied to the systematic distribution of mineral substances, but to determine the conception of their exterior, and to fix a method of describing them; that the external characters, previously employed by mineralogists, were very indefinite, and that the perfection and utility of the external description of minerals depended on a complete definition and arrangement of the external characters. This work of Werner soon became popular in Germany, but it was several years before it became more extensively known. A French translation, by Picardet, appeared in 1790, and one in English, by Mr. Weaver, was published in Dublin in 1805. In his native country it appears to have earned Werner a reputation, for in the year following its publication (1775), we find him appointed professor of minerals in the School of Mines at Freiberg, and inspector of the mineralogical cabinet at that place. He held these offices for seventeen years.

In 1780 Werner published a translation of Cronstedt's Mineralogy, with notes, and in the following year a catalogue of the privately collection of minerals of Papst d'Ohain. In both these works he introduced his method of distribution and descriptions of minerals according to his terminology, giving the name 'Oryctognosy' to the study, while he termed the knowledge and science of the positions of minerals and fossils in the crust of the globe, and the classification of rocks and the inferences to be drawn as to the period and circumstances of their origin, 'Geognosy.' Although in the former department Werner has done great practical service, it is in connection with the latter division, and his theory of geology, that his name must be always associated. 

In 1787 Werner published a little work on the classification of rocks, 'Kurze Klassifikation und Beschreibung der Vol. XXVIII.'
der verschiedenen Gebirgsarten, 'a brief but valuable arrangement and description of rocks,' says Dr. Pitton. The author there points out the mineralogical distinctions of rocks, but the work contains none of Werner’s theoretical views respecting formations, and the classification he has given in it was materially altered by him at a subsequent period. Werner professed to teach a theory of the formation of the primitive and other rocks by chemical precipitation from water; and in the same year, 1767, from an examination of the Erzgebirge (or Ore-Mountains), in Saxony, and the basaltic rocks of the neighbourhood, he also made an application of this doctrine whilst the origin of trap rocks. Raspe, a German, had as far back as 1768 described the basalt of Hesse as of igneous origin. To Werner’s limited sphere of observation, his erroneous opinions on this and on other subjects may in some measure be attributed. He found the basaltic mists of Saxony and of Hesse forming the summits of the hills in tabular masses, and not occurring in dykes and veins, or extending downwards into the valleys, and hence some of the strongest proofs by which these rocks are now universally admitted to be of igneous origin were present in the phenomena which came under his actual observation. But many even of the appearances in the neighbourhood of Freiberg, Werner appears to have overlooked or misconstrued. Thus within a day’s journey of his school, the porphyry, cut by granite, has been seen with its ancient veins or dikes through strata of the coal formation, but to relieve them in mass. The granite of the Harz mountains, on the other hand, which he supposed to be the primitive mass, is now thrown out and breaches the other beds, penetrating even into the plain (as near Goslar); and still nearer Freiberg, in the Erzgebirge, the mica slate does not mantle round the granite, as was supposed, but abuts abruptly against it. (Leyel.)

These views of Werner were soon followed by the promulgation in his lectures of his Theory of Formations, which, of all that he taught, we are inclined to select as his greatest achievement in the science. His ideas respecting the division of rocks into great classes we have seen to be erroneous, but he was right in regarding the masses or strata that constitute the surface of the globe present themselves in groups or assemblages, the members of which are generally associated wherever they occur, and are so connected as to exhibit a certain unity of character. Thus he terms the formations, and taught that the exterior of the earth consists of a series of these formations laid over each other in a certain determinate order. This was a most startling announcement when we consider what a small portion of the globe had undergone a change of this kind, but he was not the first to have been an author of this bold theory had little practical acquaintance. But if this reflection increases our surprise, it must also increase our admiration for the sagacity with which announced such an idea, combated and resisted at the time, now receives the assent of all geologists, and which extended observations in all parts of the globe confirm. Ideas of this magnitude are, says Cuvier, the true characteristics of genius.

Unfortunately, however, but as the natural consequence of his notions respecting basaltic and other rocks, now deemed of igneous origin, he included the latter among his series of constant universal formations, and it is almost miraculous that this part of his theory has not been effectually disproved as the rest has been confirmed. Werner taught that these formations, including his primitive rocks, as well as his flats or secondary rocks, were produced by a series of precipitations and depositions from the ocean; whilst the igneous, which have covered the globe, and, existing always more or less generally, contained the different substances which have been produced from them. In almost necessary connection with this hypothesis, he supposed a number of successive and parallel changes in the level of the sea, of very great extent.

In November, 1791, Werner published his ‘Theory of the Formation of Veins,’ which he had also taught for some years previously in his lectures. In this work he conjectured the existence of the fissures by supposing mountains to have been formed in the manner above stated, namely, by deposition from the sea of beds one above another, and that the mass of these beds being at first wet, and possessed of little tenacity, the mountain yielded to its weight, cracked, and sunk down on the side where support was wanting; and that as the waters also, which assisted in giving them support, began to lower their level, the mass would more readily yield to its weight, and continue to sink till it was broken into fragments. The shrinking of the mass in drying, and the operation of earthquakes, might, he supposed, have further assisted in the production of such rents. Having thus accounted for the origin of the fissures, he believed, and endeavoured to prove, that the veins were introduced into them from above, and that the mass of veins has been formed by a series of precipitations from water, which have filled, in whole or in part, the spaces or fissures; that these precipitations entered by the superior parts of the rents and were directed below, as water is poured in water, generally chemical, which covered the country in which these rents existed. To account for the high degree of crystallization which prevails in the veins, he supposed that the precipitations and depositions which formed them were made with a more gentle temperature than the last produced beds and formations; that mechanical solutions and depositions had disturbed the formation of veins much less than of beds, and that the spaces in which veins are found preserved for a longer time the facility of receiving and retaining different solutions. (Payfair, ‘Edin. Review,’ vol. xviii.)

A French translation of the work, by D’Aubuisson, appeared at Paris in 1802, and an English translation by Dr. Playfair, London, 1803, was intended to accompany the work Werner wrote. It is said he had a most singular aversion to the mechanical act of writing, which he carried to such an extreme as never to reply to letters, and which even deterred him from reading them, lest he should be tempted to make alterations.

In 1782 he was appointed Counsellor (Bergrath) of the mines of Saxony. Von Charpentier held the situation of Captain-general (Berghauptmann) in the same establishment, and there appears to have been a feeling of rivalry between them which lasted to observation. Von Charpentier were principally confined to the practical details of mining. In 1797 or 1798 Werner introduced into his lectures the doctrine of a new class of rocks, to which, as lying between the primitive and secondary or flint, he then the name of tertiary was given by him, and which of the distinct formations or rocks of all these classes to which assigned precise relative places, was between thirty and forty. The establishment of the transition class completed Werner’s labours, and the promulgation and further illustration of his doctrine were attended with success. During this time acquired a great celebrity throughout Europe as the first geologist and mineralogist of the day, and was looked upon as the founder and author of mineralogy as a science. His fame was not so much acquired through his writings as by means of his lectures. Indeed, some of his principal views were only promulgated in this channel. He was an admirable lecturer. One of his pupils describes his appearance in 1799 as very remarkable and striking at the first interview. He was middle-sized, and broad-shouldered; his round and friendly face did not at first sight promise much, but when he began to speak, he at once commanded the most marked attention. His eye was full of fire and animation, his voice from its force, yet its gentleness and the singularly rare, yet weiged; a cautious clearness and the most marked decision in the views he expressed were apparent in all that he said. With all this there was united a good feeling which irresistibly won every heart. In mineralogical classification he attached too much importance to the most trivial variations in the mixtures of colours occurring in minerals, all the characters of which were classified with extreme minuteness, and every instance of deviation from his arrangement, and every case of doubt, vexed and perplexed him; and yet, in the most refined figures, the same formula in the arrangement of his crystals, afterwards so successfully adopted by Hallé, yet the crystalline structure, the number of cleavages, and their relative position were
materials in Werner's classification. Whether, under his instruction, undertook a mountain expedition, received an
extremely minute plan according to which he was to
make his observations. Every deviation, even the slightest,
from the rules thus laid down, and every neglect of any
portion of them, was severely blamed. It was necessary
that he who wished to derive advantage from Werner's
instructions, should enter into himself of the
whole system was so intimately linked together, and
the various elements of discrimination in mineralogy were so
closely united with the mode of observation in geology,
that the disturbance of any of them rendered all the
other useless and void.

(Professor Steffens, Woch Erlebte.)

He considered minerals under their chemical, economic,
and even geographical aspects, and he arranged his
collections under these different modes of treating the
subject. From this, he once heard, devoted them to or
as the business of their lives.

(Cuvier, Eloge de Werner; Lyell, vol. i.)

This extended and popular treatment of the science,
struck some, while others to whom the love of science
was a sufficient inducement, became
his pupils from the connection that his lectures, from the
situation he filled, necessarily had with mining. Among
his pupils or attendants on his lectures may be
enumerated Alexander Humboldt, Von Buch, D'Aubuisson,
Junker, Freiherr von Wrangell, and others.

The saucy plains of Tartary and Africa, he would say, retained their inhabitants
in the shape of wandering shepherds; the granite moun-
tains and the low calcareous and alluvial plains gave rise to
the character of the remaining offshoots.
The history even of languages, and the migration of tribes,
had been determined by the direction of particular strata.
The qualities of certain stones used in building would lead
him to descant on the architecture of different ages and
nations, and the physical geography of a country fre-
quently invited him to treat of military tactics.
The charm of his manners and his eloquence kindled enthusiasm
in the minds of his pupils; and many who had intended
at first only to acquire a slight knowledge of mineralogy,
were afterwards employed between his walls. And
he would often urge his pupils that recourse must be had to acquire a perfect
acquaintance with the details of their preceptor's views, and
the gradual extension of his theories and discoveries.
That Werner's powers of external discrimination were
extremely acute, we have seen in speaking of him as a
mineralogist, and his talent and tendency for classify-
ing were in his mineralogical studies fully fed by an
abundant store of observation; but when he came to apply
them in his geological studies to a system, so fostered, appears to have been too strong
for the collection of facts he had to deal with. As we have
seen, he promulgated, as representing the world, a scheme
collected from a province, and even too hastily gathered from
the province of Saxony, in which he saw
some measure compensated for other deficiencies, and
enabled him to give the character of a science to what
had been before a collection of miscellaneous phenomena.
The ardour of system-making produced a sort of fusion,
which, however superficial, served to bind together the
mass of incoherent and mixed materials, and thus to form,
though by strange and anomalous means, a structure of no
small strength and durability.

(Whewell, History of the Inductive Sciences, vol. iii.)

Elected him one of their eight foreign associates, and
the leaders of the French republic sent him a diploma as

The latter honour perplexed Werner, deeply
suffered. He was so devoted to his country that he never
married, and, though the most tempting offers were repeatedly made to him.

Werner suffered for many years uninterruptedly from
a stomach complaint. He was anxiously careful about his
health, was always warmly clothed, and the stove in his
rooms was lighted through the winter. The destitution of
his country, consequent upon its being made the theatre of
the campaign of 1813, seem to have preyed upon his
mind, increased his malady, and produced a complication
of diseases from which he never rallied. In 1817 he
went to Clevey, in the latter honour perplexed Werner, deeply
sufferings. He became worse, and died there on the 30th
of June, in the arms of his sister, in the sixty-seventh year
of his age. Böttiger pronounced his funeral oration: Ritter
delivered his 'Eloge' at the Academy of Munich, and
Baron Cuvier an Academy of Sciences in Paris.

Werner was never married. He had surrendered in his
lifetime the whole of his valuable collection of minerals,
comprising upwards of 100,000 specimens, and also a large
number of Werner's mineralogical medallions, to the
Mines at Freiberg, for 40,000 crowns, a price considerably
below the value; and in consequence of the distressed
state of Saxony at that period, he accepted only a small
part of the reduced sum, reserving a moderate interest
in it, to meet the remaining expenses of his widow. Werner
laid the plan of a work on the mineralogy of the
Saxony, and, on his death, his books and papers were
bequeathed by his widow to the University of Jena.

WERNER GERODE, or STOLLBERG-WERNER GERODE, is a district or domain, with the title of a county, in

Prussian Saxony, the property of Count Stollberg-Werner
Gerode. It is between 90 and 100 square miles in extent, in-
cluding a part of the Harz and the Brocken Mountain, and is
the property of the Elector of Saxony, and is a state
of Brunswick, and the kingdom of Hanover. The
was covered with wooded mountains, round the Brocken,
which is in the centre.

WERNER GERODE, the capital of the county, in 51°
59" N. lat. and 12° E. long. is situated at the northern
part of the Harz, and is traversed by a stream called
the Zillerbach. It is a walled town, with 4 gates, and has a
suburb called Neenscherode. The mansion of the count is
an ancient castle, built on a rock 627 feet above the level
of the sea, and 40 feet below the top of the
Brocken. It is very fine prospect, and contains a library of 30,000 volumes,
including a remarkable collection of 2000 bibles, and the
archives of the county. An extensive park adjoins the
count's residence. The town is a very healthy
district, and is enlivened by being inhabited, of all the offices of the
county, by the influx of travellers visiting
the Harz, and by its woollen and linen manufactories, its
tanneries and brandy distilleries, a paper-mill, several
oil-mills, saw-mills, &c.
The town contains 4 churches, an orphan asylum, a poorhouse, and a gymnasium, and has a
considerable trade in corn. Population 5400.

(Müller, Worterbuch des Preussischen Staates; Hassel,
Handbuch; Brockhaus, Conversations Lexicon; Stein,
Handbuch.)

WERST, or VERST, the Russian itinerary measure,
being 3000 English feet, or nearly two-thirds of a mile.
From the number of vers or versst its third, and also one for every 225 versst, and the result will be near enough to
51° 40' N. lat. and 6° 37'
E. long., at the junction of the Lippe with the Rhine, a
which here forms an island, very strongly fortified, and
a citadel built by the Great Elector. It is a fortress of the
first rank, and has sustained several sieges. Wesel is an
antient town, and was formerly a member of the Hanseatic
League. Wars and other calamities greatly reduced it:
and in 1630 it had only 4000 inhabitants. Since then its
gradually recovered, and the population is above 11,000,
besides the garrison. The town has a gymnasium, a semi-

G 2 6
nary, a commercial institution, a botanic garden, and several schools. There are three German Protestant and two Roman Catholic churches, one French Calvinist and one English church, a synagogue, and numerous public buildings, the most remarkable of which are the large and handsome service-houses, the government-house, the arsenal, and the house of correction. The commerce is considerable. The manufactures are of many kinds: calicoes, linen, woollen cloths, hats, gloves, stockings, leather, tobacco, soap, and spiri-tuous liquors. Hassel says there are 100 distilleries. The inhabitants earn on a considerable trade in corn, timber, coals, potashEs, salt, cattle, wine, brandy, and colonial productions. The harbour is safe and convenient; and there is a bridge of boats over the Rhine, and a standing bridge over the Luppe. A monument in memory of the death of the captain of the gull Schill, who were shot by order of Napoleon, which is erected in a meadow near the town, was dedicated with great ceremony on the 31st of March, 1835.

WESSEL, Upper, is a walled town in the government of Coblitz, on the Rhine, the bed of which is deep and narrower than at any other point. There are two churches and three chapels, of which St. Werner's chapel is worthy of notice. The inhabitants, 2600 in number, are engaged in the manufacture of woollen cloth and the salmon fishery of the river. The town is situated on an island, in the adjacently country. On a steep mountain without the town are the ruins of the great and very strong castle of Schönburg, and below the town the perpendicular Lurley rock, celebrated for the remarkable echo.

WESER, one of the largest rivers of Germany, is formed by the junction of the Werra and the Fulda: the Werra rises in Saxe-Hildburghausen, and the Fulda in the Harz. The course of the Werra is 175 miles, and that of the Fulda 125, to their junction at Hanüversch-Münden, where their united streams take the name of the Weser, which is supposed to be only a corruption of the original name of the Werra (Wiszara, Wizara); it flows westwards, and after a junction of the Harz, forms the westward course of the Elster and the Visurgis. The Weser then passes through the principality of Göttingen (Hanover), the duchy of Brunswick, the principality of Calenberg (Hanover), the county of Schaumburg (Hesse-Cassel), the Prussian province of Westphalia, the Hanoverian provinces of Hoya, Verden, and Bremen, and the territory of the city of Bremen, from which, to its very broad mouth beyond Bremerlehe, it forms the boundary between Hanover and Oldenburg, where it is again divided, possessing both banks of the river, and falls into the North Sea 45 miles distant from Hanover. The course of the Weser from Hanover to the mouth of the Werra: its entire course from Münden is 223 miles. Its principal affluents are, on the right hand, 1. the Aller, with the Oker and the Leine; 2. the Wumm; 3. the Lune; and from the left hand; the Au; 5. the Hunte. The principal towns and ports on its banks are: Münden, Compel, Carlsahfen, Holzmünde, Hameln, Rinteln, Prussian-Münden, Nienburg, Bremen, Elsfeth, Brake, and Bremerhafen. The general direction of its course is from south to north, at first through a mountainous country to the celebrated Porta Westphalica (between four and five miles above Münden), which is a gap in the Stüntel-Gebirge, probably formed by the action of the river, through which it now flows, having Jacobseburg (528 feet high) on the right, and Wesertal on the left; the active jet of the water is 61 feet below the level of the sea. Passing the Porta Westphalica it flows through a wide valley with low banks. The facilities afforded by the navigation of the Weser, as well as of the Werra, the Fulda, and some of the other tributary streams, as the Aller, as well as the officers of the State of the number of the banks, the commercial banks, all the monies of the countries on their banks. The upper and middle portions of the Weser arc indeed often rendered impracticable for months together in the summer time by the sand-banks, and its bed becomes more and more choked by sand, so that large vessels are exposed to danger. Two miles below Bremerlehe a harbour was constructed, in 1816, at the mouth of the river.

In former times the commerce of the Weser was impeded by the numerous tolls levied by the governments of the districts bordering on the Weser. The trade on the banks (there were two bridges near Münden and Elsfeth, at all which toll was levied), by the right of staple claimed by different towns, and by a multitude of vexatious charges estab-

lished by privileges and imperial grants. The princes interested in the navigation of the river attempted by means of conferences, in 1606, 1700, and 1710, to remove some of those impediments; but nothing was effected either then, or when the subject was resumed in 1803. The Hanoverian government was then, in 1814, of effecting some important improvements. At length the Congress of Vienna, having decreed the regulation of the navigation on the German rivers, a commission, consisting of plenipotentiaries from Prussia, Hanover, Brunswick, Hesse-Darmstadt, Oldenburg, Lippe-Detmold, and Bremen, met at Hanover in 1821; and on the 10th of September, 1823, the act for the navigation of the Weser was signed. By this act the navigation of the Weser from Münden to the sea was declared free of tolls; the free ports were created, and the tolls and lands were abolished, and a uniform Weser toll was established, the amount of which was fixed for the whole course of the river. With respect to the commerce of the Weser in general, it embraces chiefly linen-yarn, wool, rape-seed oil, the productions of the Harz, Hanoverian linen, tobacco, leather, English manufactures, train-oil, window-glass, looking-glasses, and all kinds of colonial produce. The city of Bremen has long had for three centuries the first and most important share of the commerce of the country.

WESLEY, JOHN, was the most distinguished member of a family, several of the other members of which how- ever also claim to be shortly noticed, either on their own account or in consequence of their connexion with him. John Wesley was the son of Mr. Samuel Wesley, born under one head, and to take them in chronological order. The Wescleys, or Westleys, as they formerly spelled their name, are said by Dr. Adam Clarke, in his 'Memoirs of the Wesley Family,' to have believed their progenitors to be of English extraction, and of English stock. It is suggested that they might possibly have been of the same stock with the once famous reformer, John Wesselinus, otherwise de Weselis, or Basilius, of Groningen, who died in 1480. (See Biographical Notices of the Rev. Bartholomew Westley, &c., in the Post, and, in 1821, and Wessel.) Supposing the name to be English, or Anglo-Saxon, a doubt has been entertained as to whether it is properly Westleigh or Wolseleigh. There is reason to believe that the family name of Wolseleigh (probably derived from Wolsey's Hall, below, in Northamptonshire), was formerly generally passed into Westley, Wood, in the Athenæ Oxonienses, has a notice of a bishop of Kildare, of the early part of the sixteenth century, whom he describes as Walter Wolsele, generally called Westley; and it is known that when John Wesley was a boy at Westminster School, an Irish gentleman, Garret Wellesley, Esq., of Dungannon, M.P. for the county of Meath, considering the boy to be of his own family, offered to make him heir if he would have relinquished the intention of proceeding to the universities, became ejected from the first of the government; he fled to the United States, there to the late Marques Wellesley and the present duke of Wel-lington.

The Reverend BARTHOLOMEW WESTLEY is the first of John Wesley's descendants of whom there is any distinct record. He was born about 1616; was educated at one of the universities, where he studied both divinity and medicine; became, in the time of the Commonwealth, minister of Charnouth and Catetherton (two adjoining villages near to Dorking), and was ejected from the first of these livings immediately after the second on the passing of the Act of Uniformity in 1662. He continued to reside at Charnouth, practising physic, till the passing of the Five-Mile Act in 1660 drove him, with other nonconformists, to a secluded spot at Pinney, now known by the name of Whitechaple, and there he is believed to have spent the remainder of his days, which appear not to have been many, though we do

Digitized by Google
not find the date of his decease stated. ‘He lived several years,’ Dr. Calamy tells us, ‘after he was legally silenced; but the death of his son made a very sensible alteration in the father, so that he afterwards declined apes, and did not long survive him.’

The Reverend John Wesley, M.A., son of Bar-
tholomew, was born about 1630, and studied at New Inn Hall, Oxford, where he applied himself particularly to the Oriental languages, and adopted the opinions as to church and state which he joined the Moravian and the University of the university, the celebrated Dr. Owen, who is said to have shown great kindness for him. After preaching for some time to what was called ‘the gathered church’, at Weymouth, and at the neighbourhood village of Dorchester, he received his ordination, and on 24th December, 1651, ordained deacon, was elected and carried to prison at Blandford, and was exchanged for time; and soon after he got out, the Act of Uniformity deprived him of his living, and left him for several months a wanderer and an outcast. At length, in May, 1663, a passport was given him, and during the time of his residence in the village of Preston, a few miles from Weymouth. At one time he thought of emigrating to Surinam or Mary-
land; but finally resolved that it was his duty to re-
main at home. He continued to preach when he could find a place to do it, often to a crowd of fifty or sixty people, and he eventually united himself as pastor to a small con-
gregation at Poole, though without going to reside among them. He was often apprehended while thus engaged, and, besides being several times fined, was subjected to frequent imprisonment. In 1667 he married Miss Annesley, of her own accord left the Dissenters, and at the early age not full thirteen, after having, as she intimates in the preface, thoroughly examined the controversy between them and the established church. Another daughter of Annesley (who had originally held a living in the church, and was ejected by the Act of Uniformity) was the first wife of the eccentric John Dunton, publisher, and author, in whose curious autobiographical performance entitled his ‘Life and Errors’ there are several notices of his brother-in-law; and Dunton published for Wesley the first part of his octavo, entitled ‘Maggots, or Poems on several subjects’, which appeared in 1695. Wesley, besides being already married to Miss Annesley, appears to have been at this time an established writer, though only anonymously, for the bewellers.

When the Revolution took place, we are told that Wes-
ley wrote a book in defence of it; but as neither the date nor even the title is given, we may be permitted to suspend our belief as to the existence of this alleged work. As it is said to have been dedicated to the king, we may be justly influenced in our decision. The next is that, we are told, the author the living of Ewpton, in Lincolnshire, about 1693, it may possibly have been anything concerning the Revolution, but an heroic poem, in folio, entitled ‘The Life of Christ’, which he published the one year and dedicated to her majesty, and which was reprinted, with large additions and alterations, in 1697.

The Reverend John Wesley, M.A., son of Bar-
tholomew, was born about 1630, and studied at New Inn Hall, Oxford, where he applied himself particularly to the Oriental languages, and adopted the opinions as to church and state which he joined the Moravian and the University of the university, the celebrated Dr. Owen, who is said to have shown great kindness for him. After preaching for some time to what was called ‘the gathered church’, at Weymouth, and at the neighbourhood village of Dorchester, he received his ordination, and on 24th December, 1651, ordained deacon, was elected and carried to prison at Blandford, and was exchanged for time; and soon after he got out, the Act of Uniformity deprived him of his living, and left him for several months a wanderer and an outcast. At length, in May, 1663, a passport was given him, and during the time of his residence in the village of Preston, a few miles from Weymouth. At one time he thought of emigrating to Surinam or Mary-
land; but finally resolved that it was his duty to re-
main at home. He continued to preach when he could find a place to do it, often to a crowd of fifty or sixty people, and he eventually united himself as pastor to a small con-
gregation at Poole, though without going to reside among them. He was often apprehended while thus engaged, and, besides being several times fined, was subjected to frequent imprisonment. In 1667 he married Miss Annesley, of her own accord left the Dissenters, and at the early age not full thirteen, after having, as she intimates in the preface, thoroughly examined the controversy between them and the established church. Another daughter of Annesley (who had originally held a living in the church, and was ejected by the Act of Uniformity) was the first wife of the eccentric John Dunton, publisher, and author, in whose curious autobiographical performance entitled his ‘Life and Errors’ there are several notices of his brother-in-law; and Dunton published for Wesley the first part of his octavo, entitled ‘Maggots, or Poems on several subjects’, which appeared in 1695. Wesley, besides being already married to Miss Annesley, appears to have been at this time an established writer, though only anonymously, for the bewellers.

When the Revolution took place, we are told that Wes-
ley wrote a book in defence of it; but as neither the date nor even the title is given, we may be permitted to suspend our belief as to the existence of this alleged work. As it is said to have been dedicated to the king, we may be justly influenced in our decision. The next is that, we are told, the author the living of Ewpton, in Lincolnshire, about 1693, it may possibly have been anything concerning the Revolution, but an heroic poem, in folio, entitled ‘The Life of Christ’, which he published the one year and dedicated to her majesty, and which was reprinted, with large additions and alterations, in 1697.
Another folio volume of verse, under the title of 'Elegies on Queen Mary and Archbishop Tillotson,' followed in 1685; 'The History of the New Testament in Verse, with 180 sculptures, by Sturt,' 12mo., in 1701; and 'The History of the Old Testament in Verse, with 162 sculptures, done by J. Sturt,' 12mo., in 1704. In 1705 Wesley published a poem on the battle of Blenheim, for which he was presented with a medal by Marlborough, on which he characteristicly inscribed, 'Let him charge one of the regiments then stationed in England, and would, it is said, have procured him a prebend, had it not been for the influence of the Dissenters at court and in Parliament, which was powerful enough not only to prevent this promotion, but also to prevent his being elected to a prebend in the chapel of St. Paul's. In the next reign however he received and held with Epworth the small living of Wroote in the same county. He died 30th April, 1728; and the same year appeared, under the care of his eldest son, his master's degree at Oxford. He had graduated at Oxford in 1703, was ordained to the chaplaincy. In 1724, was ordained to the prebend, and in 1725, and graduated as M.A. in 1726 (pp. 42 and 47). Bouthrey's account, which is probably to be followed down to March, 1726. In the end of the same year he was appointed Greek lecturer and moderator of the classes.

From his earliest years Wesley had been of a serious temper, and more especially from the time of the commencement of his residence at college religious impressions had taken a strong hold on him. It is related that two books in particular, which he read in the course of his preparations for ordination, produced a powerful effect on him—the 'Meditations of Saint Augustine' and the 'Rules of Saint Benedict.'

Wesley's relations to one of his Brothers, Mr. G. G. Wesley, were very reduced, and the latter's account of this period is somewhat slurred. In 1707, he and his brother John, who was then in his twenty-eighth year, were both received into the Society of Dissenters. From this time Wesley began to keep a diary, a practice which he continued to the end of his life. A large portion of this record, under thetitle of 'Meditations,' has been published in a volume, and has been several times reprinted.

Soon after he was ordained, he went to officiate as curate to his father at Wroote, and here he resided for about two years; during which time, in 1728, he received priest's orders from the same presbytery from which he had been ordained deacon. It appears to have been in the end of this year that he was summoned back to college, in consequence of a regulation that such of the junior fellows as might be chosen moderators should perform the duties of their office during two years. In the latter part of this period he was an undergraduate of Christ Church, one of a small association of students already distinguished in the University by the derisive appellations of the Holy Club, the Godly Club, the Bible Moths, the Bible Diggs, the Sacramentaries, and the Methodist. At the same time, their religious enthusiasm only carried them the length of devoting Sunday evenings to the reading of divinity, the other nights being given to secular studies; but very soon religion became the sole business of their meetings; they communicated their views to one another. At their age they were ten years old, it seems, in the system of prayer, meditation, and self-indulgence; in these they indulged to a great and abstracted extent, so that the world such was his character as passed by the most rigid order of monastic devotees. John Wesley appears to have immediately joined this society, which now consisted of about fifteen individuals, of whom the most remarkable, besides the two brothers, were Mr. Morgan, whose mortifications are supposed to have shortened his life, James Harvey, the well-known author of the 'Meditations,' and George Whitefield, who shares with Wesley the fame of having been one of the two chief founders of Methodism.

It was very soon after this that Wesley became acquainted with William Law, the author of the 'Serious Call' and of other similar works; the two brothers used to travel from Oxford on foot two or three times a year to visit Law and their other friends. But they were not of this time, nor of this age. Wesley, at the age of twenty, declined at last to fly. Most of this had happened during the absence of the two Wesleys on a short visit to their parents, in 1732. In these circumstances, when the next year, it was proposed that he should apply for the next presentation to his father's living of Glastonbury, John Wesley came to the conclusion that it was his duty rather to remain at the University, as the field where
his exertions were most needed, and where also they were likely to find the greatest stimulus. Nevertheless a few months after his father's death he was induced to go out with General Oglethorpe to Georgia, where he preached to the settlers and Indians in the colony which the general was founding there. He and his brother Charles, who now took holy orders, sailed from Gravesend 14th October, 1735, in the same vessel with a party of six and twenty Moravians, and on the 6th of February, 1736. Charles returned to England, sent home by Oglethorpe with dispatches, early in the next year; John remained in America till his close. The Moravians had in the meantime begun the affair in which he became involved with Miss Sophia Causton, niece of the chief magistrate at Savannah, whose partiality he so frequently, but whom he eventually, on the advice of his Moravian friends, declined to yield. He was brought to trial for breach of his marriage vows. Wesley's journals or other private papers. As for himself, we are told, he 'kept his word, and cautiously avoided and concealed everything which could bring any inconvenience on this gentlewoman.'

He reached England 1st February, 1736. While he had been abroad, the religious excitement which now began to be generally known by the name of Methodism had made great progress in London, Bristol, and other parts of the south of England, and the management of this new church seemed to have been one of the missions which the Lord had prepared for him. The Moravians, who had broken off his intimacy with Miss Causton, it seems, the plot was revealed to him, under a promise of secrecy, by another young gentlewoman, then also recently married to the surgeon of the colony. 'Sir,' she is made to say to him, 'I have not revealed this to you which I now ashamed to mention. Both Miss Sophia and myself were ordered, if we could but succeed, even to deny your acquaintance. The biographers, we presume, have got all this out of Wesley's journals or other private papers. As for himself, we are told, he 'kept his word, and cautiously avoided and concealed everything which could bring any inconvenience on this gentlewoman.'

WES 231
after followed by Wesley at the same place, the neighbourhood of Bristol. The first separate meeting-house for the Methodists was begun to be built in the Horse Fair, near St. James's church, before the 12th of May in that same year. Lay preaching, of which the first example had been set by an individual named Bowers, in Islington churchyard, after a sermon by Whitefield, was, not without some hesitation, sanctioned by Wesley soon after his return; for is not a pleasant sight, in this part of the country, the particular gavoie to Methodism in most people's eyes the distinct appearance of a schism in the church. Accordingly, when, before the end of the year, Wesley's mother pressed his acquiescence in his views, his son Samuel wrote to her expressing the exceeding concern with which he had heard that she had countenanced the spreading delusion so far as to become 'one of Jack's congregation.' The old lady had, like her son John, been decided in a morning from that time continued to live with him, and to attend his ministry, till her death in 1742.

In July, 1740, Wesley solemnly separated himself from the Moravians, with whom he had now come to differ, or rested nowhere, seldom having less on some fundamental points of doctrine; and soon after he had met Count Zinzendorf, the two paring, say his official biographers, 'without the least prospect of a reconciliation.' Their last interview took place in Gray's Inn Walks. His object in this, as in all his dealings with the Moravians, who made the two parties immediately bitter enemies, was followed before the close of the same year by a breach with Whitefield, which however, although it divided the new religionists into two permanently distinct bodies, only excited the one more hatred and mutual regard of the two fathers of Methodism.

From this time Wesley's life was spent in preaching, travelling, writing books, and labouring in all other possible ways for the consolidation and extension of the new church, the management of which he now trusted to his own hands. No man ever gave himself up more entirely to any object, or prosecuted it either more zeal and determination, or more method and skilful management. He met an hour, some one minute, was abstracted from the service of the cause on which he had set his heart; and rarely has any ambition been so well seconded by the other qualities and habits of mind, and, it may be added, of body too, necessary to sustain it and give it full effect. The marriage turned out a very unhappy one: Wesley, who had stipulated that he should not preach one sermon nor travel one mile the less on account of his change of condition, was little at home: the lady became jealous; she and him of his substance, as he states in one of his letters, to his preacher, 'to be a weariness to bad women; and committed sundry other extravagances and outrages. Wesley had high notions of the authority of a husband, and the superiority of his own sex: 'Know you,' he wrote to her, 'that you can never engender me to more, saperme no more, provoke me no more; do not any longer contend for mastery, for power, money, or praise; be content to be a private, insignificant person, known and loved by God and me. Attempt no more to abridge me of my liberty, which I claimed the liberty of God and man; &c., &c. . . . Of what importance is your character to mankind? If you were buried just now, or if you had never lived, what loss would it be to the cause of God?' The end was, that after she had several times run away from him and been induced to return, she repeated the experiment once more, and was not asked to come back. 'Non cem religii,' says Wesley in his journal.
'non dimisi, non revocabo—I did not forsake her, I did not dismiss her, I will not recall her.' This was in 1771. She lived for ten years longer, and died at Camberrill, where a stone is placed at the head of her grave in the churchyard, setting forth that she was 'a woman of exemplary integrity, a tender parent, and a sincere friend.' She bore no children to her second husband.

Wesley died after a short illness at his house in London, on the 2nd of March, 1791, in the eighty-eighth year of his age. His publications are far too numerous for a list of them to be attempted; and even a selection of them: among the most remarkable, besides his Journal, are—a corrected translation of Thomas-à-Kempis, said to have been published by him in 1735, a short time before his death; a collection of such of his sermons as of years, of which however were written by his brother Charles; a History of England; a short Roman History; Primitive Physic; and many short tracts on theological subjects. There are at least two collected editions of his works: one in 32 vols. 8vo., printed immediately after his death; another in 16 vols. 8vo., printed in 1809. The 'Arminian Magazine,' now called the 'Methodist Magazine,' was established by Wesley in 1730, and was conducted under his superintendence so long as he lived.

Some of his sermons have been written of Wesley, the two principal are that compiled immediately after his death by Dr. Thomas Coke and Mr. Henry Moore, to which all his manuscripts were left, and published in one volume, 8vo., in 1792; and that by the late Dr. Southey, in 2 vols. 8vo., in 1820. Prefixed to the latter is a list of the chief printed materials for the biography of this extraordinary man.

The Reverend Charles Wesley, the younger brother of John Wesley, was born at St. Albans, and was educated at Westminster School under his brother Samuel, his school-bills there for several years being discharged by the relation or namesake who, as related above, offered to make him his heir if he would accompaniment him to Ireland. Charles was elected a fellow of Peterhouse in 1731, from this time his history makes part of that of his brother, with whose labours in the diffusion of his religious views and in the establishment of Methodism he was associated from their commencement. It was contrary to the scheme of life he had laid out for himself which he spent his days at Oxford as a tutor, that he was prevailed upon, in 1735, to take orders, and to accompany his brother to Georgia. After their return from America, they had occasional differences upon points both of doctrine and practice, but these were soon amicably adjusted and ended.

Charles was married by his brother, at Garth in Brecknockshire, to Miss Sarah Wynne, a lady of a good family in that county. After his marriage he confined his ministrations almost entirely to London and Bristol. Charles Wesley was married to Mrs. Flora, and his brother to Miss Sarah Moore, in their Life of his brother, 'a remarkable talent of uttering the most striking truths with simplicity, truth, and brevity. He early showed a turn and talent for writing in verse; and most of the new hymns published by Wesley in his various collections were of Charles's composition.' 'In these hymns,' observes his brother, in one of his prefaces, 'there is no doggerel, no botches, nothing put in to patch up the rhyme; no feeble explorers. Here is nothing buried or bombast on the one hand, or low and creeping on the other. Here are no cant expressions, no words without meaning. Here are (allow me to say) both the purity, the strength, and the elegance of the English language, and at the same time the utmost simplicity, the utmost truth, the utmost power, which is a just character of Charles Wesley's poetry, both in his hymns and other compositions. Harmoniously as the two brothers co-operated throughout their lives, they were very unlike in character. Charles appears to have been nature, as it were, a harmonious dike or barrier of affection or love of management and power; and, with all his sincere and fervent piety, so far from any inclination towards asceticism, as to be rather a lover of laughter and other joyous emotions, which his brother counted it almost a sin to indulge. Charles died in London on the 29th of March, 1788. Two of his sons, whom (contrary to his brother's wish) he had educated as musicians, became very distinguished in their profession.

WESLEY, CHARLES and SAMUEL, sons of the Rev. Charles Wesley (see the preceding article), are both entitled to our notice as remarkable instances of a distinct and unquestionable manifestation of musical genius, during almost the earliest period of infancy.

The Honourable Daines Barrington, who has devoted several pages of his 'Miscellaneous Works' to the youthful Wesleys, tells us that on the announcement of the father that the eldest, Charles (born in 1772), could 'play a tune on the harpsichord readily, and in good time, when he was only two years and three-quarters old,' that when he was three years old he was able to take his place on the chair, for fear of his falling. Whatever tune it was, he always put a true base to it. He became a fine performer on the organ and harpsichord; at a time however when the art of playing on keyed instruments, and particularly in England, was far from being so developed as it is at this day, he did not only have a knowledge of the way which is in the present day, and only advancing to that state of perfection which it has since reached. He early in life was brought under the notice of George III., who was much pleased with him, and he had the honour to entertain the king, in hours at royal leisure, by his performance of Handel's music. He was also much patronised by the upper classes, for the sake of his practical skill, and highly esteemed by all for his moral worth, for the simplicity of his manners, and his amiable qualities; but, as he was not selected as an object of cultivation in institutions of genius, the flattering promises of his youth were not fulfilled in future years. After attaining a certain degree of excellence as a mere performer, he remained stationary; and, as regards composition, left not to believe, any on a par with many who had had no education of any sort. He held during many years the appointment of organist to St. George's, Hanover Square. He died unmarried in 1815.

Charles Wesley was born in 1766. 'The seeds of harmony,' says Mr. Barrington, 'did not spring up in him quite so early as in his brother, for he was three years old before he aimed at a tune. His first was "God save great George our King," and such-like, mostly picked up from the floor, as no doubt a base to them till he had learnt his notes.' We may here add, that Mrs. Wesley—a very sensible woman, whose testimony may safely be relied on—toled Mr. Barrington that she had had 'an elder son, who died in his infancy, and who both sung a tune and played the harpsichord was to be sent to Oxford. Samuel from his cradle enjoyed the advantage of hearing his brother's performances on the organ, and his superiority may undoubtedly be partly ascribed to this circumstance. He was not five years old when Handel's compositions were first produced in public. Charles at eight years old, continues the same, 'when Dr. Boyce came to see us. . . . He had by this time scrawled down his oratorio of "Ruth."' The doctor looked over it very carefully, and seemed highly pleased with the performance. His father wrote, 'Thus far I have seen: this boy writes by nature as true a base as I can by rule and study.'

The young musician was now introduced into all companies as a prodigy. He was placed under the instruction of every body, including the most distinguished musicians. Mr. Barrington fills pages in recounting the marvellous things he not only did, but said; for that acuteness which was so striking a feature in him when a man, was not less conspicuous in a child. He being not capable of eight years of age he received some instruction on the harpsichord as well as in composition, and at the same time studied the violin, to which instrument he devoted much time, and completely mastered it. In 1777 he published eight lessons. He was a great walker, with much pleasure, and so much notoriety that his portrait was engraved, and is said, by Mr. Barrington, to have been a strong resemblance.

We have understood that he began to consider music as his profession when he had arrived at his twelfth year, and have in vain endeavoured to trace his history during his progress from adolescence to manhood. Concerning his general education, we must suppose that it was attended to carefully, for he was a good Latin scholar, was not igno-
had successfully cultivated that taste for polite literature which he may be said to have inherited. From personal knowledge we can state that his conversation was that of a man of letters accustomed to the best society. His steady friend, Mr. W. Linley, introduced him to Mr. Sheridan at his villa in Surrey, where he passed two days, the party consisting only of those three. That great wit and musician, Mr. College, full of wonder at his ease and his company, said to his host, ‘I am no judge of Mr. Wesley's musical abilities, but I will venture to assert that his intellectual powers and education would have enabled him to distinguish himself in every walk of life.’

Mr. Wesley's prospects were early clouded by an accident he met with in 1767. In passing along Snow-Hill one evening, he fell into a deep excavation which had been prepared for the foundation of a new building. It is supposed that the severe injury he sustained was the source of that state of mind which subsequently checked the progress of a career that promised to be so brilliant. During seven years he continued in a low desponding state, refusing the solace even of his favourite art. On his recovery however he turned it with renewed vigour, and then brought into notice the works of Sebastian Bach, at that time alike unknown here and on the Continent. In 1815 he suffered a relapse, and was again obliged to retire from public life during another period of the same desolation. Until 1822, and up to 1830 was much engaged in various professional pursuits. The disease then recurred, and it was evident that his constitution was undergoing a great change. He now began to devolve his work. The Saturday immediately preceding the day of his death he exhibited his extemporaneous powers to a friend, and composed some psalm-songs. On the Monday he took to his room, under a presentiment that he should never be in it more. He died two days after, on October the 11th, 1837.

Mr. Wesley produced many compositions, but few of them were calculated to please the multitude. He wrote a grand mass for the chapel of Pope Pius VI., for which the sovereign pontiff himself is said to have been pleased. He also made his amende to the Protestant church by composing and publishing a complete Service for the use of our cathedrals. It must however be granted that, as a musician, his celebrity is greater on the Continent than in his own country, that arises from his performances on the great organ excepted, for which he was better known here than by his printed works. He left a numerous family.

[Barlington's Miscellanies; Gentleman's Magazine, 1837.]

WESSEL, JOHN, Latinized WESSELIUS, a Dutch divine, was born at Groningen in 1419. At an early age he lost his parents, and was educated by a charitable lady, who afterwards sent him to the college of the priests of St. John at Groningen, and, at the age of twenty, he took orders, though this has been said. He continued his studies at Cologne, where he pursued with great zeal the theological works of the Abbot Rupert, the MS. of which was in a convent at Deutz, opposite Cologne; and being an accomplished Greek and Hebrew scholar, he undertook to purify his religious knowledge by reading the original sources of the Christian religion. He was soon suspected of heterodoxy, and for this reason the university of Heidelberg, where Wesley went to teach divinity, would not admit him among the professors, on the ground that he was not a doctor of divinity, and that they could not confer this dignity upon him because he was a layman. Wesley consequently left Heidelberg, and lived some years at Cologne, where he made himself a great name by his private lectures on divinity and philosophy. His philosophical system was that of Aristotle, and his power of argumentation was so great that few doctors ventured to engage in disputes with him. Wesley made himself no less known at Cologne by his sermons in the church, and he attacked abuses with such as much boldness as learning and shrewdness. From Louvain he went to Paris, then the theatre of violent disputes between the Realists, the Formalists, and the Nominalists. He was suspected by his adversaries, but at last he became a Formalist himself. Notwithstanding this change of principles, he maintained his name as one of the greatest dictators of his time, and as much the public voice recognised him by the surname of 'Magister Contradictiorum,' which was probably given to him in Paris. A divine possessing the learning, the talents, and the character of Wesley might have attained the highest dignities in the church, but he was one of the Husites who were defending their religious principles for seventeen years against the thunders of the Vatican and the armies of the Holy Roman empire; and when this war and the degenerate state of the church led to the general election of Pius II. in 1458, and the election of Pius II. to the See of Rome, general of the Minorites, who became afterwards pope under the name of Sextus IV., made the acquaintance of Wesley at an early period, and continued to be his friend and patron. It is said that Wesley accompanied Francis de la Rovere to the Council of Basle, which met in 1431, and was finished in 1443. Wesley must have been very young when he went there, unless he was born in 1398, as some say, though the best authorities agree that he was born in 1419. Francis de la Rovere, having been chosen pope in 1471, told his friend Wesley that he was ready to bestow any favour upon him which he should desire, and asked him if he would accept a bishop's see; but Wesley declined honours and dignities, demanding but a Greek oratory, and was enabled to retire from the library of the Vatican. After a sojourn of several years at Rome, Wesley returned to Groningen, where he died on the 4th of October, 1480.

Wessel is frequently called a forerunner of Luther, and justly so, inasmuch as he tried to eradicate abuses and errors, and to restore the Christian religion to its original purity. It seems that the doctrines of Wicklif had great influence upon him. But there is this remarkable difference between Luther and Wessel: Luther attacked the foundations of the Roman Catholic system; Wessel only wrote against particular doctrines, such as purgatory, the ban, indulgence, &c., and he took his arguments from the philosophical systems of the middle ages quite as often as from the simple truth of the Bible. He was a man suspected of heresy, and after his death some monks at Groningen burnt a valuable part of his manuscripts. Wessel argued, that the pope was not infallible, and that general councils alone were. His principal productions were: a sermon against mea non, 1, De Sacra Eucharistia; 2, De Purgatorio et Judi-mentiis; 4, De Dignitate et Potestate Ecclesiastica; 5, Propositiones de Potestate Papae et Ecclesiae. &c. He wrote also numerous notes and additions to the works of the Abbot Rupert, and used to call his voluminous production 'Mare Magnum.' The editio princeps has the title 'Farrago Romani Theolagorum,' Leipzig, 1522, reprinted at Basel, 1523. Luther, who esteemed Wessel very highly, pronounced his works on election and excommunication; theeditio princeps is not complete. The first complete edition was published at Groningen, 1614, 4to; 2nd edition, Amsterdam, 1617, 4to. Some of Wessel's treaties are contained in the first volume of Goldast, 'Monarchia Sacri Romani Imperii.'

WESSELLING, Peter, one of the first scholars of the eighteenth century, was born on the 7th of January, 1692, at Steinfurt, the capital of the present principality of Ben-themein Steinfurt, in Prussian Westphalia, where he received his first education. In 1712 he went to the university of Leyden, where he studied the classical languages under Pe-rizonius, Gronovius, and Wesseling; and in 1714 he went to the university of Franeker, in West Friesland, where he finished his studies under Vitrivius, Andala, and Bosius. His first intention was to study divinity, but he soon devoted himself to philology. In 1717 he was appointed corrector of the library at Middleburg, with the right to keep for himself six old books. In 1720 he was appointed praelector or professor of history and eloquence in the lyceum of Deventer; and in 1723 he became professor of history and eloquence in the university of Franeker, which office he held during eight years. In 1725 he was appointed professor of Greek, and was conferred his degree of doctor in the same year. In 1732 he became director of the public library at Utrecht in 1750, or perhaps as early as 1749. Hensterofts invited him to teach at Leyden, but Wesseling preferred stopping at Utrecht. Wesseling was rector of the university of Franeker in 1753, and twice, in 1760 and in 1769, he was chosen to the Senate of the University of Franeker in 1753, and twice, in 1760 and in 1769, he was chosen...
rector of the university of Utrecht. He died on the 9th of November, 1764. His reputation as a scholar and a sagacious critic was great. Yet he was little disposed to critical investigations, till his friend and colleague at Franeker, Hemsterhuy, succeeded in persuading him, as Ruhnken states, that no learning, however pure and profound, was of any use unless it were guided by criticism. Wytenbach calls Hemsterhuy, Valckenier, and Wesseling, the triumvir of philology.

The principal works of Wesseling are: 1. An edition of Dionysius the Areopagite. Amsterdam, 1738, fol. 2. This edition contains the prefaces of Henry Stephens and Rhodomann, and the Latin version of Rhodomann, revised by Wesseling, who collected valuable materials, such as the notes of Camust, and of several other scholars: De la Barre at Paris, Nonnus at Brussels, and Prothomianni at Rome, who examined for Wesseling the manuscripts in the libraries of those three cities. The Bipont edition of Diodorus Siculus is little more than a reprint of the edition of Wesseling, though it contains the notes of Heyne and Eyring, who had access to two MSS. at Vienna, which were not used by Wesseling. 3. An edition of Herodotus. Amsterdam, 1769, fol. Wesseling had collated the best MSS. of England, Paris, and Vienna, and several at Rome which were in the possession of Passioni, or to which this learned cardinal had access. The Latin text was compiled by Steijn, the Latin Laureativity, and the notes of Gale, Gronovius, Valckenier, and of the editor: it was considered the best edition of Herodotus, till that of Schwäighäuser appeared in 1816. 4. *Dissertatio Herodotica*, Utrecht, 1758, 4to, treats on several portions of Herodotus and on several other subjects connected with Herodotus. 5. *Veterum Romanorum Itinerarium*, Amsterdam, 1735, 4to, contains the Itinerary of Antoninus, that of Jerusalem, and one of the Itineraries of Hierotheus. It had been published by Bandurius, in his *Imperium Orientale*. This is a useful edition. 6. *Observationum Variorum Libri Duo*, Amsterdam, 1727, 8vo, 2nd edition, by Professor Frotscher, Leipzig, 1832, 8vo, contains various notes on Dion Cassius, Ammianus Marcellinus, Sophocles, Plato, and other Greek and Roman writers. Besides several other valuable works, such as *Libri De Judaeoarchontibus*, *Notae ad Samuellis Petiti Leges Atticae*, &c., Wesseling wrote eight orations in classical Latin, among which are the following: *Oratio de Origine de Pontificiae Dominio*. Wesseling, 1741, fol.; *Oratio in Obitum celsissimae et regiae Principis Annae, Foederat. Belgic. Gubernatrice*. Utrecht, 1793, fol.; and nineteen *Dissertationes*, among which are *Dissertatio Historiocrata* MS. kept in the University of Utrecht; *Dissertatio Medico Theologic* de Origen et Progresso Religionis Christianae in Veteri Persarum Regno; and *Epistola ad H. S. Reimarum*, qua selecta quaedam Dionis Cassii locum partim emendatam, partim ornatam, suppl. Amsterdam, 1739, 4to. A complete copy of the work. Other productions of Wesseling is contained in *Elogium Wesselingi*, in Frotscher's edition of Wesseling's *Observationum Variorum Libri Duo*. Wytenbach, *Vita Davidis Ruhnkeni*, p. 40; David Ruhnken, *Elogium Tertiari Hemsterhui*, 2nd ed., 1780, p. 60, &c. *Strondinm, Das Neue Gekhrte Europa*, pars iv., ix., xx.; Wesseling's Preface to his edition of Herodotus.

WEST, GILBERT, was the son of the Reverend Dr. West, by whom an edition of Pindar was published at Oxford in 1627, and who died in 1718; his mother was Mary, the eldest of the three sisters of Sir Richard Temple, afterwards Lord Cobham; the second of whom, marrying Mr. Richard Grenville, succeeded her brother as Viscountess Cobham, and was afterwards created Countess Temple; and the third of whom marrying Mr. Richard Stratton, was the first lady of Great Grimsby, afterwards the Countess of Long Crendon in Buckinghamshire, of whom was Colonel James West, the friend of John Hampden, and who were descended from Lord Delaware, renowned in the wars of Edward III. and the Black Prince. Benjamin's birth was on 15 October, 1690. He was taught the rudiments of reading in the fields near his mother's residence by Edward Peckover; the subject was the corrupt state of the old world and its imminent destruction. Mrs. West was carried to illness, and Benjamin was born after an illness of twelve days. The peculiar circumstances of his birth, various surmises and prophecies regarding the child's future destiny, and those which promised his future greatness were credulously cherished by his father. The first indication West gave of his talent was in his seventh year,
when set to watch the sleeping infant of his elder sister. He drew a sort of likeness of a child in black and white, a feat which appeared so wonderful in the eyes of his parents, that they recalled to mind the predictions of Peckover. When he was about eight years old, a party of Indians paid a visit to Springfield, and struck with the drawings young West had made of birds, fruits, and the like, they taught him to prepare the red and yellow colours with which they stained their weapons; and these, together with the indigo given him by his mother, with the aid of some hair-pencils supplied from his mother's favourite card-maker, the young pensmith quickly acquired a art which his pen-and-ink sketches had been. A merchant of the name of Pennington and a cousin of the Wests saw some of these attempts, and upon his return home he sent his young cousin a box of colours with pencils, canvas, and six pencils. Young West from this time foresook school and almost shut himself up with his presents in a garret, which he converted into his studio. He made a picture from two of these prints, and Galt, West's biographer, saw this first likeness and exclaimed: 'Ay! Here is the painting of Christ rejected; and he relates that West told him that there were touches in that first essay which he had never surpassed.

In his ninth year West accompanied his friend Mr. Penny and his wife on a journey which he afterwards described as a 'tailor.' He was about to take a ride with a schoolfellow to a neighboring plantation. 'Here is the horse,' said the boy, 'be quick and get upon him, he is yours, and don't frighten him,' said Benjamin. 'I'll ride behind nobody.' 'Oh, very well,' said the other; 'I will ride behind you.' He mounted, and away they rode. This was the first journey he was ever on, and he immediately declared that the next day he would set out to go to Rome and learn to be a painter. 'A tailor,' exclaimed West; 'you will surely never be a tailor.' 'Indeed but I shall,' returned the other; 'it is a good trade. What do you intend to be, Benjamin?' 'A painter.' 'A painter! what sort of trade is a painter? I never heard of it before.' 'A painter,' said West, 'is the companion of kings and emperors. You are surely mad,' said the other; 'there are neither kings nor emperors in America.' 'Ay, but there are plenty in other parts of the world. And do you really intend to be a painter? I believe there is nothing surer.' 'Then you may ride alone,' said West, leaping down; 'I will not ride with one willing to be a tailor.' West's first patron was Mr. Wayne, who gave him a doiion for three poplar-boards upon which he had drawn some figures; and he was at the same time assisted by Dr. Morris, who gave him some money to purchase prepared pannels with. Another patron was Mr. Flower, a justice of Chester, in Pennsylvania, who took young West for a short time to his house, where he made the acquaintance of a young English lady, governess to Mr. Flower's daughters, who told him stories of Greek and Roman history, which the young painter listened to with enthusiasm, and often expanded in conversation. West's first attempt, which attracted much notice was the portrait of Mrs. Ross, of Lancaster, a neighboring town. This led to many other portraits, and a grumihist of the same place requested him to paint a picture of the death of Socrates. West said he could not paint a picture of the death of Socrates, for he was to do with the slave who prevented the poison, who, he thought, should be naked. The grumihist answered his question by going to his shop, and returning with one of his workmen, who was half naked, and offering him as a model. The picture was painted, and attracted much attention.

Upon his return to Springfield, when he was about sixteen years of age, the propriety of his following professionally such a vain and sensual occupation as that of a painter was canvassed both in the Quaker community. But after they had satisfied themselves of the distinction between the use and the abuse of the art, they agreed unanimously that in his case they might suspend the strict operation of their tenets; and his becoming a painter by profession was sanctioned by the whole Quaker community of Springfield. Shortly after this event, West served as a volunteer under Major Sir Peter Halket, and went in search of the remains of the army which had been lost under General Braddock. But from this service he was soon called home by the illness of his mother, and he arrived just in time to see her die. After this event, which he by a great deal of art, left his home, and established himself, then only in his eighteenth year, as a portrait-painter at Philadelphia. He charged two guineas and a half for a head, and five for a half-length. He painted at this time his picture of the Trial of M. D'Angehna. For this, Mr. Pennington made him a portrait from a drawing, which was hung up in his shop, and doubled his prices. Here he had an opportunity of going to Rome, a journey he had long desired to make. Mr. Allen, a Philadelphia merchant, then at New York, was about to send some corn to Leghorn, and he offered West a passage in the vessel. West had saved some money, with which added to a cheque for fifty guineas, that Mr. Kelly, a merchant of New York, gave him in a letter to his agents at Philadelphia when he sat to him for his portrait, besides paying him for the picture, enabled him to undertake the journey. He arrived at Rome in July, 1760, and was well received. When he was introduced, by Lord Grantham, to the old Cardinal Albani, who was blind, as a young American who had come to Rome to study the arts, the Cardinal asked him whether he was learning this art for what purpose. He answered that West was learning it as an American, because he thought that an American, as an American, could have seen nothing of art, were anxious to see what effect the noble works of antiquity would have upon him; and, says Galt, 'thirty of the most magnificent epigraphs in the capital of Christendom, a visit to the Louvre, a tour through Europe, conducted the young Quaker to view the masterpieces of art.' It was agreed that the Apollo should be first submitted to his view. The statue was enclosed in a case; and when the keeper threw open the doors, West exclaimed: 'Mr. Galt, is not this the warrior!' The Italians were surprised and mortified with the comparison of their noblest statue to a wild savage; and West perceiving the unfavourable impression, promptly removed it to another room. He described the Archivolt, the natural elegance and admirable finish of the work, the elasticity of their limbs, and their motions free and unconstrained. 'I have seen them often,' he continued, 'standing in the very attitude of this Apollo, and pursuing with an intense eye the arrow which they had just discharged from the bow.' This criticism was afterwards repeated as one of the best that was ever pronounced upon the Apollo.

West however soon attracted other attention than that of mere curiosity. He painted a portrait of Lord Grantham, which was placed in the gallery of Crespigny, where artists and amateurs used to meet. The picture was almost universally supposed to be by Mengs, and all were greatly surprised when they heard that it was painted by a young American. The most prominent among them was West that he had no occasion to come to Rome to learn to paint; and he advised him immediately to visit the principal cities of Italy, and examine the various great works in them, and then to return to Rome and paint some historical picture. An illness prevented West from putting this plan into execution; he was confined through a fever eleven months at Leghorn. When he recovered, instead of being without means, he found to his great astonishment that his agent had orders to give him unlimited credit. He owed this to the generosity of two Philadelphia merchants, Mr. Allen and Governor Hamilton. He now pursued the plan recommended by Mengs; and after he had examined all that was worth studying in Florence, Bologna, and Parma, he returned to Rome, and painted two pictures, which were well received; one of Cicero and Iphigenia, and one of Angelica and Medora. He was elected a member by the academies of Florence, Bologna, and Parma. Of the works of Raphael and the masters of Rome he has expressed the following opinion: 'Michael Angelo has not succeeded in giving a probable character to any of his works, the Moses perhaps excepted. The works of Raphael grow daily more interesting, natural, and noble.'

In 1763 West visited England on his way back to his own country; and in London he had the good fortune to meet three of his best friends, Messrs. Allen, Hamilton, and Dr. Smith, who had always taken great interest in him. He soon made connections by the help of his friends,
and the two pictures mentioned above, and a portrait of General Monkton, second in command to Wolfe at Quebec, all of which he exhibited in town, procured him a few commissions. He painted the portraits of Prince and Andromache for Dr. Newton, and the Return of the Prodigal Son for the bishop of Worcester. Lord Rockingham offered him 700l. per annum to decorate his mansion in Yorkshire; but this offer, by the advice of his friends, he declined. He next went to Ireland, where he had the honor to introduce Drumsmond, a young American lady, he requested her to come over to him, England, which she did, and they were married a short time afterwards.

West's good fortune seemed to keep pace with his years. Dr. Drummond, the archbishop of York, commissioned him to paint a picture of Agrippina landing with the Ashes of Germania; and the prelate was so well pleased with the performance, that he attempted to procure the painter an annuity by subscription, so as to enable him to desist from painting portraits and to confine himself to historical subjects. He proposed to raise 3000l., and he and his friends subscribing 1500l., he however failed in the enterprise, but he raised both the painter and the picture to high rank. He had nearly forty years' intimacy with George III. West's excellence as a painter however was not the only source of his good fortune; he was an excellent skater, and acquired numerous friends through his accomplishments. When the Serpentine river in Hyde Park was frozen over, a great circle of spectators was frequently seen to admire the young American painter cutting the Philadelphia salute.

The picture of Regulus was exhibited in the first exhibition of the Royal Academy, of which West was one of the principal members; he had previously been a member and director of the Society of Artists, incorporated in 1765. But his death of General Wolfe was the first work which established his high reputation as a painter. His portraits in Greek and Roman costumes, as was usual, he very sensibly painted them in their own dresses; an innovation which Sir Joshua Reynolds had tried to dissipate him from. The following is, according to Galt, West's account of this subject. He says, 'When I was understood that I intended to paint the characters as they had actually appeared on the scene, the archbishop of York called on Reynolds, and asked his opinion; they both came to kneel down before me from running so great a risk. Reynolds began a very ingenious and brilliant dissertation on the state of the public taste in this country, and the danger which every innovation incurred of contempt and ridicule, and concluded by urging me earnestly to adopt the costume in the greatest part of my subject than the modern garb of European warriors. I answered, that the event to be commemorated happened in the year 1758, in a region of the world unknown to Greeks and Romans, and at a period of time when no warriors who wore such costume existed. The subject I have to represent is a great battle fought and won, and the same truth which gives law to the historian should rule the painter. If, instead of the facts of the action, I introduce historic dress, how shall I be understood by posterity? The classic dress is high and grand, and is not lost in sentiment what I gain in external grace. I want to mark the place, the time, and the people; and to do this I must abide by truth.' They went away then, and returned again when I had the painting finished. Reynolds seated himself before the picture, examined it, and 'said minutely, and for half an hour; then rising, said to Dmmond, "West has conquered—he has treated his subject as it ought to be treated—I retract my objections. I foresaw that your picture will not only come on to the most popular, but will occasion a revolution in art."' West was now thoroughly established both in the king's favor and in that of the public, and he continued to produce in rapid succession a series of large and in many respects excellent portraits, and it was thought that the great reputation he acquired was relatively well merited, though his works will not bear comparison with those of the great masters of Italy. Lord Grosvenor purchased the picture of the Death of Wolfe, and West made a copy of it for the king. He painted also for the king, the Death of Epaminondas as a companion to it; the Death of the Chevalier d'Eon; and the Family of the King of Armonia; and Segestus and his Daughter brought before Germanicus. He painted the following series of large historical works for George III. at Windsor:—Edward III, embracing the Black Prince, after the battle of Cressy; Francis I, in the battle of Guat; the Black Prince receiving the King of France and his Son prisoners at Pojects; St. George killing the Dragon; Queen Philippa defeating David of Scotland in the battle of Philip's Oak; the Duke of Orleans, Edward for the Burgess of Calais; Edward forcing the passage of the Somme; and Edward crowning St. Eustace de Ribamboul at Calais.

After the completion of these works, West proposed to the king to paint a picture on the subject of the Progress of Revealed Religion; but his majesty, before consenting to this proposal, consulted some of the dignitaries of the church as to the propriety of introducing paintings into a place of worship: Bishop Hurd answered for himself and colleagues, and said that the objection of religion. To myself that your majesty's chapel could in no respect violate the laws or usages of the church of England. Out of thirty-five subjects proposed by West, all were approved of by the bishops: he afterwards added another to the number. He divided the theme into the four parts of antiquity, the archal, the Mosaic, and the Prophetic. Half of the subjects were from the Old Testament and half from the New. They were all sketched, and twenty-eight of them were executed, for which West received 3000l. He painted in the other eight the portrait of the royal family, for which he received 2000 guineas.

After the death of Reynolds, in 1792, West was unanimously elected president of the Royal Academy, and the king sent the Duke of Gloucester to inform him that the honour of knighthood would be acceptable to him. 'No man,' said West, 'entertains a higher respect for political honours and distinctions than myself, but I really think I have earned greater eminence by my pencil already than I have rendered myself, and titles is to preserve in families a respect for those principles by which such distinctions were originally obtained—but simple knighthood to a man who is at least as well known as he could ever hope to be from that honour, is not a legitimate object of ambition. To myself that your majesty's highness must perceive the title could add no dignity, and as it would perish with myself, it could add none to my family. But were I possessed of fortune, independent of my profession, sufficient to enable my posterity to maintain the rank which I have acquired, the title might become a desirable object. As it is however, that cannot be, and I have been thus explicit with your royal highness, that no misconception may exist on the subject.' The duke is believed to have distinctly understood this, and said, 'You have justified the opinion which the king has of you; he will be delighted with your answer.'

In 1801, during the illness of George III., West met with perhaps the first serious illness of his life: Mr. Wyatt, the royal architect, called upon him, and told him that the pictures painting for the chapel at Windsor must be suspended until further orders. 'This extraordinary proceeding,' says his biographer, 'rendered the studies of the night part of his day, and using it I so lost in sentiment what I gain in external grace. I want to mark the place, the time, and the people; and to do this I must abide by truth.' They went away then, and returned again when I had the painting finished. Reynolds seated himself before the picture, examined it, and said, 'West has conquered—he has treated his subject as it ought to be treated—I retract my objections. I foresaw that your picture will not only come on to the most popular, but will occasion a revolution in art.'
to receive it, he was told it had been stopped, and that the paintings for the chapel, of Revealed Religion, had been suspended. He submitted in silence—he neither remonstrated nor complained.' During the thirty-three years which West worked for George III best; there is a 24,140

the distributions of prizes. As literary compositions these discourses are nothing remarkable, and they are chiefly distinguished for their simplicity and common sense. The British Institution arose out of a favourite plan of West's, and the strength and novelty of his recommendation of the encouragement of works of high art. There is a full-length portrait of West, by Sir Thomas Lawrence, in the National Gallery.

(Galt, Life and Studies of Benjamin West, &c.; Com- munication, Lives of British Painters, &c.; Annual Bio-

graphy and Obituary, vols. i. and v.)

WEST BROMWICH. [STAFFORDSHIRE.]

WEST INDIES is a term at present exclusively applied to the archipelago which constitutes the eastern boundary of the Gulf of Mexico; the Guianas, and the islands of the Lesser Antilles. They are divided into three groups: the Portuguese, the Spanish, and the French. The Guianas, the largest, extends from 19° to 10° N. lat., and from 50° to 60° W. long.

The most northern portion of this archipelago, or that part which is north of 20° N. lat., rests on an extensive plateau which is in some places as much as 800 feet in elevation. It exhibits a great variety of rocks and minerals, and is covered with extensive forests. The most remarkable of these rocks is that which is known as the Old Bahama Island, and divides the bank into two nearly equal parts. To the north and north-east of it is the Great Bahama Bank, and the Bahamas Islands; and on the south of it the West End Bank, and the West Bank.

The Old Bahama Channel is connected at its north-western extremity with the Florida Straits by two arms, enclosing the Florida Bank, of which the northern is called the Sotaren Channel and the southern Nicholas Channel. The Florida Straits themselves ought to be considered as the northern continuation of the Old Bahama Channel, as they divide the Bahamas Bank from the continent of North America.

In the language of sailors the Old Bahama Channel is considered as terminating in the east between the small Island of Cuba, and the island of Henegaus (the Inagua of our maps); but in a more comprehensive view, we must include in it the deep sea which separates the minor banks north of Hayti from this island, so that it extends to the Moni Bank, in one line with the island of Cuba, which is the northernmost of the Greater Antilles.

The most narrow portion of the Old Bahama Channel is between 22° and 23° N. lat., where its width hardly ever exceeds twelve miles.

The Bahamas Bank consists of the Great and Little Bahamas, and six smaller banks, which lie to the south-east of Great Bahamas Bank. Little Bahamas Bank, the most northerly of all, extends about 100 miles from north-west to south-east, and is between 30 and 40 miles wide. Along its eastern edge is the Island of Alacran, on the southern that of Grand Bahama. Between this bank and Great Bahamas Bank is Providence Channel, which unites Florida Straits with the Atlantic, and is from 20 to 40 miles wide. Great Bahamas Bank extends about 300 miles north-west to south-east, and is about 100 miles wide, so as to cover an area of about 45,000 square miles. But a considerable portion of this surface is occupied by two remarkable inlets of deep water, which extend parallel to one another in the longitudinal direction of the bank. The east inlet opens into Providence Channel, and is called the Tongue of the Ocean. Near its entrance are the islands of New Providence and of Andros. The second inlet is the deep water.

The Inlet of the islands of St. Salvador, which is the first place where Europeans landed in America. This inlet is called Exuma Sound, from the island of that name, which is situated towards the southern end of the island, and are best seen in May and June, being then surrounded by innumerable islands, which lie along it in a row, and extend over more than 80 miles. The outer edge of the bank,
that which is turned towards the Atlantic, is in nearly its whole extent raised above the surface of the water; and here are three large islands, Eleuthera, St. Salvador, and Long Island, of which the first is more than 80, the second about 60, and the last about 70 miles long. There are no islands along the inner edge of the bank, or that is washed by the Florida Straits, Santanent Channel, and Old Bahama Channel, with the exception of a few rocks, which are hardly above the surface of the sea.

The minor banks are situated south-east of Great Bahama Bank, and in number, of which however only three contain islands. The first is the Bank of Crooked Island, which is separated from the Great Bahama Bank by Crooked Island Passage, through which the vessels generally pass when going from the West Indies to Europe. This bank extends hardly more than 50 miles from south-west to north-east. It has the form of a triangle, and its edges are formed by islands, except towards the south-west. The largest islands are Crooked Island and Akin's Island. Between Crooked Island and the Caicos Bank, is a wide opening of the sea, which lies due north to the Windward Passage, or the wide strait between Point May in Cuba and Mole St. Nicholas in Hayti. In this wide opening are the islands of Grand and Salt Cay (Jamaica) and St. George (Barbuda), with a few smaller ones, which differ from the other Bahama islands in rising much higher above the surface of the sea, and not being contiguous to banks, though surrounded by reefs and cliffs. The Caicos Bank extends probably more than 60 miles from north-west to about 50 miles across; and its islands, the Caicos, lie along the north-eastern and north-western edge of the bank. Between this bank and the following, called Turk's Islands Bank, extends a strait, known as Turk's Island Passage, which is narrower than the bank itself, and contains two small but tolerably fertile islands, Grand Cay and Salt Cay. The three remaining banks, Mouchoir Carré Bank, Silver Bank, and Bajo de Navidad, contain a few naked rocks.

The extensive banks which surround the greater part of the island of Cuba prove that this island rests on a bank similar to the Great Bahama Bank. These banks surround the island to a distance of about 400 miles, and are surrounded by a bank of generally small extent, where large vessels have access. (Cuba, vol. viii., p. 394.) They generally extend from 20 to 50 miles from the shores, and in a few places even to 80 or 100 miles. The eastern portion of Cuba however is not from banks, and in these districts alone the mountains rise to a considerable elevation, whilst those parts which are surrounded by banks contain only hills. The division between these two regions may be marked by a line drawn from the southern shores to Punta Matarorro on the northern coast.

The mountainous portion of Cuba evidently belongs to another region, which extends far to the east, comprising the three other larger Antilles and the Virgin Islands; and extending almost to the coast of Hayti, but not in the western parts the mountains rise to a great elevation. The Montanes del Cobre in Cuba, to 7200 feet; the Blue Mountains in Jamaica, to 7500; and those of Cibaio in the southern, to about 8000 feet. Failing to the east the mountains in Puerto Rico they do not attain 4000 feet, and in the mountainous districts of the north 2000 feet. Those of Virgin Gorda perhaps do not exceed 600 feet. These mountains exhibit the formation of most mountains of Europe, and those of rocks are prevalent in the highest range. Between them there are valleys of considerable width, and on their sides smaller ones, all of which are very fertile. There are considerable plains, as in Jamaica and Hispaniola, which however are destitute of trees and less fertile. The mountains, their declivities, and the valleys are thickly wooded in their natural state.

The strait which lies between Virgin Gorda and Anguilla separates this region from the islands of volcanic origin, which extend from 18° 20' to 12° N. lat. and between 60° and 64° W. long. This strait is the curved line. These islands consist, either entirely or for the most part, of mountains and rocks of volcanic origin. Anguilla, which lies at the most northern extremity, and Barbuda and Barbados, which do not lie in the line of the row, but are somewhat to the north, are however not much elevated, and they exhibit no traces of volcanic action, but consist mostly of limestone rocks. The greater number of the others are entirely composed of lava or other rocks of volcanic origin; but in St. Martin, St. Barbuda, and St. Eustache, there are extensive cliffs consisting of limestone or sandstone. Two of these islands have active volcanoes: that of Guadaloupe made its last eruption in 1797; and that of St. Vincent in 1812. The others contain extinct craters or solfatara in different degrees of elevation. The Antilles, however, are not the only countries consisting of volcanic rocks, presents great and sudden irregularities. The mountains rise from 2500 to more than 8000 feet above the sea. The highest are the Morne Diabloin in Dominica (3516 feet) and the Soufrière mountain on Martinique (4000 feet), both being about 18° N. lat. The mountains are the centre of the chain. Proceeding south and north they become lower, but Mount Misery in St. Christopher is still 4854 feet, and Morne Rouge in Grenada 3840 feet high.

The northern shores of these islands, which are exposed to the winds from the north and south, are generally too short and too much exposed to the trade-wind to constitute harbours. On the western shores the Indancs are generally deep, and their declivities gradual; and here the inlets are of greater extent, and form good harbours.

The fourth natural division of the Columbian Archipelago comprehends the islands of Tobago and Trinidad, which are situated on the eastern slopes of the islands of Puerto Rico and Hispaniola, in the general line of the north-east coast of Venezuela. There are no traces of volcanic action on them, except some mud-volcanoes on Trinidad. This island consists of three ranges of mountains, including two wide plains. In Tobago there are 20 feet above the sea-level, and have gentle declivities.

Climate.—All the islands of the Colombian Archipelago, with the exception of the most northern Bahamas, are within the tropic; and their climate, as in other countries, is generally warm and equable. The trade-winds, which depend on that progress. The year is divided into two seasons, the dry and wet. All the islands which are south of 18° N. lat. have two dry and two wet seasons, and this is also the case with the southern shores of the islands of Puerto Rico and Hispaniola. The long dry season sets in when the sun approaches the southern tropic, about the end of November or the beginning of December. In this season the weather is generally very constant, and the rain indeed occurs, but not frequently; and this dry climate is continued from six weeks to seven weeks and even months in succession. This weather lasts till the sun approaches the equator. Towards the end of March a change in the atmosphere takes place in the most southern islands, and it becomes cooler in the north. The sun is then near 18° N. lat. The short rainy season begins, which in the southern islands lasts about six weeks, but in the northern only 15 or 20 days. Showers are then frequent, and sometimes several occur in one day, but they hardly exceed six months in the northern islands. But this season also begins about the 24th of May, and lasts till the sun reaches the northern tropic. In July the long rainy season sets in, and continues to the month of November. These rains, which are ushered in by violent gusts of wind, and accompanied by terrific thunder-storms, are generally not heavy in July; but they become so in August in the southern, and in September in the northern islands. They then descend in torrents, and sometimes continue for twenty-four hours without interruption; but they usually fall in

Digitized by Google
showers, several of which occur in one day, and sometimes as many as twenty. In the southern islands they begin to diminish in September, and in the northern in October. In November the showers are moderate and less frequent.

On the island of Cuba and on the northern coasts of the other Greater Antilles and the Bahamas, the seasons are not so distinctly marked. Though fine weather prevails during the long dry season, it is frequently interrupted by rain. It must however be observed that the heaviest falls fall in those months when the rainy season is the longest, in the islands lying farther south. The quantity of rain which annually falls in these countries is considerably less than in those islands where the seasons are more regular. In the former it amounts to between 48 and 80 inches, and in the latter to 60 to 80 inches.

The mean annual temperature differs very little in places situated between the tropics. In the West Indies it is about 79°, as may be inferred from the observations recorded in the following table, in which those made at Puerto d'Espana in Trinidad, the most southern island, are placed by the side of the observations made at the Havana, in Cuba, and at Nassau, in Old Providence (25° N. lat.), one of the Bahamas.

Mean annual temperature: 78°-79°-87°

But though the mean annual temperature is nearly the same all over the Archipelago, the difference between the hottest and coldest month at Puerto d'Espana is only 3 degrees; whilst at the Havana it is nearly 14 degrees, and at Nassau 10 degrees. There is of course a considerable difference in the mean temperature of the seasons, as appears from the following table:

The greatest heat experienced at Puerto d'Espana does not exceed 85°, or 15 degrees above the mean annual temperature. At the Havana the thermometer sometimes rises, but rarely, to 92°; but it sometimes descends as low as 45°, and in its vicinity ice is occasionally formed, after a long continuance of northern winds in December or January. (Cmna, vol. viii., p. 204.) With this exception, it is stated that no pro. have been experienced even on the summits of the high mountains of Cuba or Jamaica.

When the sun is in the southern hemisphere, the archipelago enjoys the full benefit of the trade-winds, blowing from north-east and east-north-east, and diffusing over it a refreshing coolness. But whenever the sun has passed the equator, the trade-winds retire to the northward as far as 15° or 16° N. lat., and are replaced by south-eastern winds, which are warm and usually gentle; they continue to blow with diminishing force till June, when they are frequently interrupted by calms which blow from all the points of the compass, and frequently in very violent gusts. This is also the season of the hurricanes, which rarely occur in July, but generally in August or September. They are now all extinct on Trinidad and Tobago, and are hence more frequent and destructive on the Lesser Antilles than in Jamaica or Cuba. In Cuba they usually occur in October. When the trade-winds are not strong, the heat is moderated by the daily alternation of the sea- and land-breezes, the first blowing by day, and the land-breeze by night. The calms between the breezes are the hottest part of the day, but they last only from one to two hours.

All the islands of the Columbian Archipelago are subject to earthquakes; but they are not violent, except on the islands of volcanic formation, where they prove sometimes very destructive, which has been the case this year in Guadalupe. The climate is considered healthy from November to June, but during the great rains various diseases, especially fevers, are prevalent.

The seas and Currents, a knowledge of the navigation of the archipelago is much affected by the currents which prevail in the surrounding seas. The Guiana or Guyana Current (Atlantic Ocean, vol. iii., p. 297), which runs from Cape St. Roque, in Brazil, along the shores of Guyana, and sets to the north-west, enters the Caribbean Sea, and runs between the islands of Trinidad and Martinique. It is strongest between Trinidad and Granada, where it runs from a mile to a mile and a half per hour, and has less strength between the last-mentioned island and St. Lucia, where it runs less than a mile per hour. Between St. Lucia and Martinique the current is reduced to 21 miles per day. North of Martinique a weak current is met with, running only from eight to ten miles per day, and hence it is considered as being only the continuation of the drift current of the Northern Atlantic. It renders the communication between the islands very tedious, especially in the season when the trade-winds are not in force, and calms prevail.

A current running in a different direction prevails along the north-eastern coast of the Bahamas. It sets along the banks to the east-south-east, and varies much in strength according to the seasons. Rennell thinks it probable that this current is only the continuation of the northern counter-current of the Gulf Stream.

In the sea between this current and the Guyana Current the extraordinary phenomenon occurs which is called the 'Ground-sea,' or, in Jamaica, the 'North Sea.' It is a swell of the sea, to which the south-eastern Bahamas, the northern-eastern coast of Cuba, and Hispaniola, but not Puerto Rico and the Virgin Islands, are subject. This heavy swell sets in generally in October, and continues, though with some interruption, till April and May. During June, July, and August it appears only occasionally, and for a short time. It takes place when the air is calm, when there has been no indication whatever of a previous gale, or even when light airs have for a considerable period come from the southward of east. The sea approaches from the north the banks of the island of Hispaniola as far as the Barbados, and the waves approach the land in masses, which suddenly rise to large ridges crested with foam, and form billows which burst upon the beach with great impetuosity. When the waves dash against cliffs, the spray often flies more than 100 feet high, and is attended with loud and tremendous resounding noises, which are carried along a rumbling noise caused by the nodules and fragments of rock which the breaker brings to the shore. Wave then follows wave in quick succession, there being only a short interval after the third. The sea for many miles from shore assumes a peculiar aspect. Different tints of blue, from the lightest to the darkest, form a strong contrast with the snowy foam of the breaking waves when they strike against the broken rock, or with the white line which is visible along the whole coast. The phenomenon of the 'ground-sea' has not been explained satisfactorily, and seems not to occur in other parts of the globe, except along the south-western coast of Sumatra, where the surf, as described by Maresen in his 'History of Sumatra,' exactly resembles the ground-sea of the Columbian Archipelago.

**Productions.—** The grains, plants, vegetables, and fruit-trees, which are cultivated either for the purpose of obtaining articles of export or as food, have been described under the several productions of the islands and are too numerous to be separately noticed.

The wild animals which existed on the archipelago when the Europeans first arrived were, the agouti, peccary, sis-<ref>co</ref>on, also or native Indian dog, and the wild hog. There are now all extinct on Trinidad and Tobago, except the wild hog, which is still common on most islands. Monkeys are still found on several islands, and in Jamaica there is a smaller kind. Birds are numerous, and nearly all of them are fit for food. There are numerous parrots, wild guinea-fowls, quails, several species of wild pigeons and...
The Swedes possess only the small island of—
St. Bartholomew.
The Island of Hispaniola, including the adjacent islands of Barba, Tortes, and Grenada, is estimated to contain—

25,000.

Population and Inhabitants.—The population amounts to 3,200,000 individuals. But it is very unequally distributed over the islands. The Bahamas, which exceed in surface the Lesser Antilles by 483 square miles, had in 1839 only 23,048 inhabitants, whilst the population of the last mentioned group exceeded 600,000. This is chiefly to be ascribed to the inferiority of the soil of the Bahamas, and to its general unfitness to produce the same, but partly also to their being settled only at a comparatively late period. [Bahas, vol. iii., p. 275.] The last-mentioned circumstance must be taken into account in forming an opinion on this subject is evident from the rapid increase of the population of the Bahamas of late years. In 1857 they had 19,948 inhabitants; and in 1890, 29,048: so that in two years the increase amounted to 3,015, or nearly to 16 per cent. In the British Antilles, on the contrary, the population has decreased since the abolition of the slave-trade, and in some of them considerably. It is however supposed that the emancipation of the slaves will increase the population in the British Antilles, though it will probably diminish the commercial produce of the islands; such has been the effect on the island of Hispaniola, whose population has certainly increased in this century, and the value of its commercial produce has been greatly diminished. The Spanish islands, which, up to the emancipation of the Spanish Main, had been neglected by the government and nation, but which, since 1815, have attracted the attention of both, have in about twenty-five years nearly doubled their population. The islands belonging to the other European nations have either remained stationary, or their population has increased, though not much.

Population of the West Indies in 1850, founded on different censuses, taken between 1830 and 1840—

The original inhabitants of these islands are extinct, with the exception of a few families of Caribs, on the islands of St. Vincent and Trinidad. The present population is com-
posed of whites and negroes, and the opening of these two races. In the tables published by government since the census of the slaves the number of inhabitants belonging to each race is separately stated, and it is therefore impossible to determine the present proportion between them. But from the census published formerly, and other facts, it is evident that in the British islands the negroes form one-fourth of the population; in Cuba, about one-half; and in Puerto Rico, three-fourths.

The proportion between the two races in the islands which belong to other European nations is nearly the same as in the British islands. In Hispaniola both races are so mixed, that the following words are often written: 'Jamaican negro.'

History.—The greater number of the islands composing the Columbian Archipelago were discovered by Columbus. On his first voyage he first fell in (12th Oct., 1492) with the island of St. Salvador, one of the Bahamas, which the natives called Guanahani. He visited also the Bahamas, and then sailed along the east coast of the last-mentioned island from Punta Maternola to Cape Mayney, where he passed to Hispaniola, of which he discovered a great part of the northern coast. His second voyage (1493) he discovered the Lesser Antilles north of 15° N. lat., and also Puerto Rico, and in the following year the southern coast of Cuba. In his third voyage (1496) he discovered Trinidad, the last part forming the western boundary of Margarita and Cuba. In his fourth voyage he discovered the Bay of Honduras and the whole of the coast of Central America from Cape Gracias a Dios to Puerto Bello, and in returning from this coast to Hispaniola, also the islands of the Grenadines. St. Vincent was then discovered, either at the same time or soon afterwards. Columbus formed the first settlement on his second voyage, and in the beginning of the sixteenth century the other Greater Antilles were occupied and settled by the Spaniards, who afterwards undertook important settlements in the commercial intercourse with these islands. But as the Spaniards did not think it worth their while to occupy the smaller islands, they became the resot of that extraordinary society of pirates known by the name of Buccaneers, which flourished in the sixteenth and still more in the following century. Thus these islands became better known in Europe, and with the assistance of the Buccaneers several nations settled permanently in them. Other islands were wrested from the Spaniards, and with his reputation, in the second half of the sixteenth century.

Several events which have taken place during this century have considerably affected the condition of the English possessions; the abolition of the slave-trade, the emancipation of the slaves, and the free intercourse not only of England, but also of other European nations, with countries producing similar articles. The possessions of other nations, except the Spaniards, have also partly been affected by some of these events.

(Bryan Edwards, History of the West Indies; Humboldt's Voyage aux Regions Equinoxiales du Nouveau Continent; Waller's Voyage to the West Indies: West India Sketch-Book; Schomberg's Old and New England; a Work Illustrated by Twenty-five Engravings, Middon, A Toolemonde's Residence in the West Indies; and Tables of the Revenue, Population, and Commerce of the United Kingdom, 1842.)

WESTALL, RICHARD, R.A., one of the more distinguished of the English painters of the late generation, was born in 1766, probably in London. In 1779 he was apprenticed to Mr. Thompson, an engraver, in the city, of heraldry on silver, but his superior abilities having been perceived by Mr. Alfoldour, a miniature painter, he was recommended by that gentleman to study drawing, and make painting his profession. He accordingly obtained leave from his master in the last year of his apprenticeship to draw in the evenings at the Royal Academy, and in 1786 he was at liberty to follow the bent of his own inclina- 

tion. He took, jointly with his friend Sir Thomas [then Mr.] Lawrence, a house in Soho Square, in the corner of Great Street, which covered the whole of a small room.

Westall's first performances which attracted the notice of the public were some highly finished historical pieces in water-colours, in which he was without a rival: of these he afterwards said—'Sappho in the Lesbian Shades, chanting the Hymn of Love; Julai, the first voice of the Lyre; the Boat that killed Adonia brought to Venus; the Storm in Harvest; the Marriage Procession (from the Shield of Achilles); besides many others.' He made also a series of very considerable designs to illustrate Milton, for Alderman Boydell; and he was a contributor to the 'Boydell Shakesperians.' He painted at the same time several large historical pictures, but he met with so little success in the disposal of them, that he was almost compelled to confine himself to making small designs for booksellers, and in the number and popularity of his designs of this class he was second only to Stothard. They added however little to his reputation, for, owing probably to the great number required of him, he fell into a peculiar and affected mannerism which detracted from all his performances. Some of his later works were much admired; one of these was 'Crabbé's Poems,' and Moore's 'Loves of the Angels.'

Westall was elected a member of the Royal Academy in 1794, the same year in which Sir Thomas Lawrence was admitted. Towards the end of the year he became very embarrassed in his means, owing to some unsuccessful speculations in foreign pictures and some imprudent partnership engagements. His last occupation was giving lessons in drawing and painting to her present majesty while Princess Victoria. He died on the 4th of December, 1836.

Although Westall's circumstances were, during the last few years of his life, not very prosperous, they were not so bad as was represented in several newspaper accounts that appeared at the time of his death; nor was there any allowance granted by the Royal Academy to his superannuated or distressed members. His sister, Miss Westall, depended entirely upon him for support, and he allowed her regularly 60£ a year until his death. After her brother's death the Duches of Kent settled an annual pension upon her of 100£.

In 1808 Westall published a book of poems illustrated by himself. As a historical painter he will never hold a place in the rank; some of his works display a fine feeling for light and shade, and a certain elegance of colouring; but his later works were extremely mannered, formal in composition, and stiff and affected in design.

WESTBURY, [Wilts.]

WESTERAA, [SWEDEN.]

WESTERAATEN, ISLANDS OF. [TROONHEIM.]

WESTERHAM, [KENT.]

WESTERIN. [SWEDEN.]

WESTERN AUSTRALIA extends over the western portion of the Australian continent, and comprehends, according to an arrangement lately made by government, all the countries lying west of 125° E. long., so that the boundary-line between the two is determined by the Greenwich meridian. This portion joins the Indian Ocean west of Cambridge Gulf and the Southern Sea, nearly in the middle of the Australian Bight. Thus Western Australia contains about one-fourth of the whole continent, and lies between 30° and 14° S. lat. and between 113° and 129° E. long.

We are particularly acquainted only with that portion where British colonies have been settled, and of which a description has been given under Swan River [vol. xxii., p. 367]. The remainder is still more unknown. Two years ago, says a correspondent, Mr. Eyre, travelled along the coast from Adelaide on the Gulf of St. Vincent in South Australia, to King George's Sound in Western Australia. According to the report that has reached us, he found this tract of coast to be nearly a useless waste, consisting chiefly of sandhills, or of a gravelly soil on which there was a scanty vegetation. It is remarkable that, in this journey of more than 1000 miles, his progress was not once impeded or retarded by any large river. Thus we
may now consider it a well established fact, that along the southern coast of Australia, which extends about 2000 miles, only one large river, the Murray, finds its way to the sea, and it seems probable that the countries adjacent to this coast on the west of the Murray River, like many other extensive countries near the tropics, are entirely destitute of rain. If this should be found to be so, this tract may be considered desert, like the Sahara of Africa.

The country north of the settlements and contiguous to the sea is certainly better, but as far as it has been explored, that is, to the vicinity of Shark Bay (22° S. lat.), it contains no large tracts of land fit for cultivation, or available for other purposes, though the surface is generally level, and in some places rises into hills of moderate elevation. North of Shark Bay, even the outline of the coast is very little known, with the exception of some projecting portions. It appears to present a much greater variety of useful products than any other part of Australia: it consists of numerous widely-projecting promontories and headlands, between which there are wide bays, and several narrower inlets, which penetrate inland to a great distance from the open sea. Some of the projecting parts are very high, and give a considerable elevation. We know very little of the natural powers of Tasman Land, as the coast only has been slightly examined, and nothing is known of the interior, even at the distance of two or three miles inland.

The low-lying portion of indifferent quality, and this is one of the reasons of the slow progress of the colony. It would however probably have improved much more rapidly in population and cultivation, if shortly after its settlement other countries in the neighbourhood, as South Australia and part of New South Wales, had not been opened to those who left their country with a view of settling in the southern hemisphere. As all these countries are more fertile than Western Australia, they have recently attracted all the emigrants from British India, and several families which formerly had settled in Western Australia have removed to South Australia and Port Phillip. It therefore cannot be a matter of surprise, when we find that the population is stationary. It consisted, in the year 1850, of 2070 individuals; and in 1833 it amounted only to 2154 persons.

No grains or roots are cultivated, except those grown in England. The principal objects of agriculture are wheat, barley, oats, rye, and potatoes, of which the average production in 1839, was 300,000 bushels, of which 30 of barley, 35 of oats, 20 of rye, and four tons of potatoes, shows that the soil, though not distinguished by fertility, will repay the labour bestowed on it. Maize is not grown, though, on the other side of the continent, in New South Wales, it constitutes an important article of cultivation. We are not acquainted with the circumstances which have prevented the cultivation of this useful grain. The progress of cultivation has been much more rapid than that of population. The cultivated area is 2,000,000 acres under crop, in 1834, which rose to 1,066,000 in 1839, and in 1839 it amounted to 2,258. More than half of this area is sown with wheat, namely, 1,481 acres (1839). Barley is also cultivated to some extent; oats and rye much less. We do not know of the attempts to transplant to this region the fruit-trees of Europe have been successful.

The domestic animals imported from Europe thrive very well, and increase rapidly, especially sheep, goats, and swine, as appears from the following table:

What has been said of the botany and zoology of Australia, in vol. iii. p. 123 and 124, is applicable at least in a great measure, to Western Australia. It does not appear that metals of any kind have been found there, but a few quantities have been opened, from which limestone and marlstones are obtained. On the island of Rottemeal, which is nearly opposite the entrance of the harbour of Fremantle, there is a salt-work, in which a moderate quantity of salt is made.

There are several harbours in the settled part of Western Australia, but only that of Fremantle at the mouth of the Swan River, and that of Albany in King George's Sound, are visited by large vessels. The subjointed table shows the number of vessels which visited these two ports in 1839, and also the countries to which they belonged.

History.—That part of the Australian continent which is now comprehended under the name of Western Australia was called, up to the end of the last century, New Holland, which name had been given to it by the Dutch navigators, who discovered all its coasts in the seventeenth century. By various expeditions it was visited more than once, until a century before that time had annually sent several vessels and even fleets to the East Indies, they never approached the coasts of Australia, because their trade lay along the eastern shores of Africa and through the Channel of Mozambique. But this changed for commercial relations with the islands of the Indian Archipelago, in the expectation of large profits from the spice trade, followed a more direct route between the Cape of Good Hope and the Sunda islands, and they soon fell in with the western coast of Australia. Dirk Hartog discovered, in 1616, the most western point of that continent, Dirk Hartoge's Island, and sailed along the coast northward to North-west Cape. The adjacent country was called by him Endrechts Land, from the name of the vessel in which he sailed. Three years later (1619) Van Edels fell in with the coast south of Endrechts Land, which received his own name, but is now called Australia. [Swan River, vol. xxiii., p. 571.] In 1822 that portion of the coast was explored by Tasman, in 1844, in his second voyage [Tasman, vol. xxiv., p. 77], and received from him the name of Van Diemen's Land, but as the large island south of Australia is known by this name, geographers have generally substituted that of Tasmania. From that time Western Australia was visited by the navigators of several nations, but never examined, except that Dampier surveyed Shark's Bay. Captain King surveyed a great part of the northern coasts, and several vessels from England's triumph, under Captain Baudin, in 1805. Captain Stirling visited the Swan River in 1823, and its favourable representations gave rise to the settlements on its banks. [Swan River, vol. xxiii., p. 370.]

WESTERWALD. [GERMANY.]

WESTMANNLAND. [SWEDEN.]

WESTMANNIA. [SWEDEN.]
WESTMINSTER. [MATH. WEST.]

WESTMINSTER, a city in the county of Middlesex, one of the constituent parts of the British metropolis, containing the royal residence, the houses of the legislature, the supreme courts of law, the chief public offices of the executive government, and the magnificent abbey church of St. Peter, which is one of the places of interment for persons illustrious by their talents, position, political character, or military and naval achievements. [LONDON.]

The city and its situation. The surveys of the City of London, and its various parishes, form a part of the eastern side by the left bank of the river Thames. The boundary leaves the river almost midway between Waterloo Bridge and Hungerford Market, and with a little deviation follows the course of the river, being represented by the line of St. George's Fields till it reaches Drury Lane; it then moves northward through Leadenhall Street and the Temple, runs in an irregular line westward, keeping to the south of Lincoln's Inn Fields till it reaches Drury Lane; it again turns northward and then northward runs by Castle Street, West Street, and the Commercial Road, to the Thames just in front of Chelsea Hospital. The area of the city is 2500 acres, the number of houses, by the census of 1831, 21,682, namely, 20,616 inhabited, 894 uninhabited, and 412 building; the number of freemen and freewomen 46,004 families, or 201,842 individuals. This statement does not include the population of the liberty of the duky of Lancaster, now added to Westminster for parliamentary purposes, or the area or position of the present county of the Savoy; both which are taken as parts of Osolston hundred in the county of Middlesex. The general description of the city is given elsewhere. [LONDON.]

In the present article we propose to give an historical sketch of its origin and of the extension of its buildings and population.

The city appears to have owed its origin to a church erected here by Sæbyrht or Sebert, king of the East Saxons (or, to follow Camden, of the East and Middle Saxons), on the site of which was afterward built the Abbey Church of St. Peter, in the supremacy of his uncle Æthelbyrht, or Æthelbert, king of Kent, and Bretwalda, or lord paramount, of the Anglo-Saxons, and had been converted to Christianity after his uncle, by the preaching of Mellitus, who was one of the companions of Æthelbert. The mission of Mellitus to the East Saxons took place a.d. 604; and as Sæbyrht appears to have died about the same time as Æthelbyrht, a.d. 616, we have an approximation to the date of the foundation of the church, which must have been some time between those two dates. Sæbyrht and his wife Aldegoda were buried in the church of St. Peter, which appears to have been afterwards called West-Minster from its position with relation to St. Paul's, the metropolis church. The early churches of London were of small size, and the antiquity of the church to a much higher period, and have affirmed that St. Peter himself visited Britain and erected a small chapel or oratory here; others, more moderate, ascribe the first ecclesiastical structure on the spot to King Æthelred, on the site of which the present abbey church was reared in the latter part of the second century, and to have built a church here from the ruins of a heathen temple which had been overthrown by an earthquake. The existence however of any church prior to that raised by Sæbyrht is, to say the least, very doubtful, and at the time when that was erected the place was in so uncultivated a state, that the Saxons called it 'Thorome,' the 'Isle of Thorns.' The island was formed by an arm of the river, called Long Ditch, now a common sewer; or probably by the removal of a body of water from the higher ground emerged, on which the church was built.

The church of Sæbyrht appears to have been destroyed by the Danes about the time of Alfred, and remained desolate until the reign of Edgar, who caused it to be rebuilt, and established in the place, about a.d. 965, a Benedictine priory or abbey of twelve monks, who were however poorly provided for. If this establishment was not an abbey from its foundation, it became one not very long after. The church nevertheless appears to have been held in high esteem, for, a.d. 1046, the body of Queen Eleanor, who died at Westminster, was brought here for burial. The body of the dead king was taken up the same year by order of his half-brother and successor Hardecanute, or Hardicanute, and thrown into a ditch. In the reign of Edward the Confessor, successor of Hardecanute, Westminster Abbey was returned to the palace built or occupied by Edward appears to have been on or near the same site as the residence of succeeding kings and of the present houses of parliament: it has been dedicated to Olave, and to St. Katherine, St. George's Hanover Square.

It is not unlikely that Westminster had occasionally the residence of the Anglo-Saxon kings before Edward's time, as Scotland Yard is said to have derived its name from a palace assigned by Edgar as the residence of a clerk of the church. Edward was buried in it, as also Editha, his wife, daughter of Earl Godwin. Edward built also a parish church, that of St. Margaret, for the inhabitants, who previously had the use of a part of the abbey church.

The parish of St. Martin-le-Strand originally comprehended the whole of the present city and liberties, with the exception possibly of the two parishes of St. Mary-le-Strand and St. Clement Danes. The boundaries of the parish as described in a judgment, a.d. 1222, by Cardinal Stephen Langton, and confirmed by the other arbitrators, on occasion of a dispute between the bishop of London and the abbots and monks of Westminster, as to whether the abbey was subject to the bishop's jurisdiction. The original judgment was given by two bishops, Epeicopis et Decanis Londinensibus et Assarvannus. The parish also comprehended several 'villae' beyond the city limits, as Knyghtebredige (now Knightsbridge), Westburne (Westbourne), and Satyngtonn (Paddington), with its church of St. Martin-in-the-Fields. Westminster Abbey was not included in the parish, though surrounded by it on every side. When this church of St. Martin was erected it is not known; it was perhaps originally a chapel of the monks of the abbey, who had a garden near the church, called the Abbey Garden, and from the churchyard was, in a.d. 1059, the common burial-place of the Danes, and in it part of the remains of King Harold I. were deposited, after being disinterred from their resting-place in St. Peter's abbey by order of Hardicanute. The Strand (so called in the Saxon Chronicle) was at this time apparently the road or street between London and Westminster, and upon it Earl Godwin and his son Harold drew up their land forces in their insurrection against Edward the Confessor, a.d. 1052. The church of St. Martin and St. Peter's, Westminster, was at the time of Langton's judgment (a.d. 1222); but how long before cannot be ascertained. St. Mary's church was then called the Church of the Innocents, or of St. Mary and the Innocents; and there is reason to think, from the notice of it in 1063, that it was the church of the parochial. St. Martin's was made parochial some time between the delivery of the judgment and the year 1063. The parish was formed by dismembering all the northern and southern parts of St. Peter's parish, which were not only the present parish of St. Martin, but also those of St. Paul, Covent Garden; St. Anne, Soho; St. James's, and St. George's, Hanover Square.

After the Conquest, Westminster continued to be the usual residence of the kings of England, and St. Peter's abbey the usual place of their coronation. Edward I. afterwards fixed in the bottom of the inauguration ceremony.
a spot which he had brought from Scotia in Scotland, the possession of which was thought to secure possession of the government of that kingdom. William Rufus built a large hall as a banqueting-room to the palace; and this, with other public works which were carried on at the same time, was made the occasion of great oppression to the people. The garden walls were thrown down in 1057, perished thereby. This banqueting-hall was pulled down and rebuilt by Richard II., and is the present Westminster Hall.

Henry III. began to rebuild the abbey church of St. Peter's, and in 1244 he commenced the antediluvian restoration of Edward the Confessor to be pulled down in a.d. 1245. He had previously built a new Lady-chapel. He was buried in the new church, a.d. 1273, and several of his successors on the throne have also been buried there. The church was not completed until after Henry's death. In a.d. 1277 that part of the abbey which had been rebuilt was much damaged by fire; and in a.d. 1303 the king's treasury, then kept in the abbey, was robbed of a vast sum (said in Allen's 'History of London,' but we know not on what authority, to have been 100,000l.); and the abbey and nearly fifty of its monks were apprehended and sent to the Tower on suspicion of being concerned in the robbery; twelve of them were detained in prison two years.

The bishop of the abbey of St. Peter's a fair and a market, which were held at Tounthill, on the west side of the abbey, a locality known in later times as Tothill Street and Tothill Fields. The woollen or wool-market, of the metropolis was also established in Tothill Fields. The court offices were in a separate portion of the place, which was then quite separate from London. Between them was the village or hamlet of Charing, the last place where the body of Eleanor, the faithful and beloved queen of Edward I., rested on the way to Westminster. Here it was that the Lady-chapel of Charing Cross, one of those erected by Edward at all the places where the body had rested, was demolished during the troubles of the reign of Charles I.; but the place where it stood has retained its name.

In the reign of Queen Elizabeth, the Lady-chapel of St. Peter's, built by Henry III., was pulled down, and in place of it was built the more extensive and costly structure now known as Henry the Seventh's Chapel. This was the last important addition or alteration made in the abbey before the Reformation, or indeed until early in the last century, when the western towers were rebuilt under the direction of Sir Christopher Wren. Since that time a considerable part of the abbey has been renovated, but no additions have been made since that time.

At the dissolution the yearly revenues of St. Peter's abbey were estimated at 3077l. 9s. 4d. gross, (Speed), or 3471l. os. 2d. clear (Dugdale). A MS. valor makes the revenue 3033l. 17s. 4d.; and according to another account (Stevens) it was 3305l. 10s. 4d. from this time the abbey had little other revenue than the abbey was considered to be the second in the kingdom. On the dissolution Henry VIII. first converted it into a college of secular canons, appointing the ex-abbot to be dean; but he soon after changed his mind, and established a bishopric at Westminster, assigning to it the county of Middlesex as a diocese, and appointing to the abbey, now made a cathedral, a dean and twelve prebendaries. This was about a.d. 1541. On the translation of the first bishop, Thomas Wriothesly, who had wasted the revenues, to Norwich, a.d. 1550, the bishopric was discontinued; but the chapter remained till the time of Mary I., who again made it a Benedictine abbey, though retaining popularly the designation of Westminster Abbey; but in the reign of Elizabeth it was made a collegiate church, with the troubless of the troubles of the time of Charles I. and the Protectorate, it has since continued to be. Westminster School is a part of the collegiate establishment, and is endowed out of the revenues of the former abbey.

At the Reformation, Westminster comprehended the parishes of St. Margaret, St. Martin-in-the-Fields, St. Clement-Danes, and St. Mary-le-Strand; and the chapel of St. John the Baptist, in the Savoy, a pre-eminently attached to the house erected by Peter, Count of Savoy, which was given by Henry III. The palace, a.d. St. Mary-le-Strand was pulled down by the Protector Somerset, in order to the erection of his mansion of Somerset House, which occupied the site; and the inhabitants long remained without a parish church, attending either at St. Clement-Danes or at the Savoy Chapel. Early in the reign of Queen Elizabeth, about a.d. 1560, according to the plan published by Vertue in 1737, Westminster was united to London by an unbroken line of buildings, extending from the palace of Whitehall at Westminster, by Charing Cross and along the Strand; those on the south side of the Strand consisting chiefly of the mansions of the nobility, with gardens extending to the river; and those on the north side, between Drury Lane and St. Martin's Lane, being also mansions, having gardens behind them; then a park or garden, apparently part of the former Convent (or Abbey) which had been given to the presentation by the neigbouring houses extending along what is now Cockspur Street to the end of Pall Mall; but the Haymarket was a country road, separated from the fields by a hedge on each side. The Mews at Charing Cross existed, and their eastern wall, with that of St. Martin's churchyard and of the park or garden, noticed as extending at the back of the houses on the north side of the Strand, lined St. Martin's Lane on each side for some distance; but the greater part of that lane was lined with hedges, and had fields on each side, which were used for feeding cattle and other purposes.

In the neighbourhood of the church of St. Clement-Danes, and at the Strand end of Drury Lane, about Clement's Inn, the houses were more thickly grouped, but the greater part of Drury Lane was skirted by public buildings, and Charing Cross, built on the site now occupied by Lincoln's Inn Fields and the neighbourhood, and on the other, the site of the present Covent Garden Market, Long Acre, and Castle Street. Hyde Park and St. James's Park and Palace were in existence at this time. Henry VII. (1485-1509) had formed the foundation of Westminster Abbey by the purchase of the former and latter site of the Savoy Abbey, which had been attached to the abbots of St. Peter's, Westminster, and had been obtained by an exchange by Henry VIII., who also erected St. James's Palace and laid out St. James's Park. Whitehall Palace, previous to the time of Henry VII., had been the residence of York, has been purchased by the same prince, in consequence of a fire which had destroyed the greater part of the old palace of Westminster. Speed's plan of Westminster, published in 1610, a few years after Elizabeth's death, gives a city but little more extensive than the plan of 1500, showing that during the reign of that princess there had been little change.

In the interval between the publication of Speed's plan and the close of Charles I.'s reign, the greater part of the buildings took place in the part of Westminster adjacent to the Strand. The greater part of the area contained within the limits of the city of Westminster east of St. Martin's Lane had been covered with streets; and westward of the Strand the irregular line formed by Wardour Street, Pulteney Street, Warwick Street, and Piccadilly nearly to the Green Park, at that time still united to St. James's Park. Lincoln's Inn Fields, the scene of Lord Russell's execution, the piazza or square of Covent Garden, now a market, Leicester Fields, now Leicester Square, and Soho Square, then called by some King Square, had been laid out and built. The city had also extended westward along the south side of St. James's Park, and southward, along Millbank, to that which forms the Lambeth shore.
Sohn Martin's had been assigned as a parish. But between A.D. 1717 and 1720, when Strype published a new edition of Stow's Survey with A Map, the buildings had ceased to be used during a tenure of 15 years by a subscriber, the Bond Street, inclusive of those two streets: toward the Piccadilly and of Old Bond Street the houses had extended westward to about Clarges and Half-Moon Streets, and along Piccadilly itself they had already reached Hyde Park Corner. Handel's GermanJaehoc was, about 1735-6, let for a term. In 1788 the buildings had extended along the whole south side of Oxford Street, and nearly the whole space between Piccadilly and Oxford Street was covered with buildings, as the result of malversation, for the sale of a western corner about Berkeley Square and Mayfair, which were not fully covered as at present till the reign of George III. The churches of St. George, Hanover Square (A.D. 1724), and St. John the Evangelist, near Millbank (A.D. 1727), had been built and made parochial. St. George's parish was dismembered from St. Martin's-in-the-Fields, and St. John's from St Margaret's. Westminster bridge had been begun, although it was not completed and opened until A.D. 1747.

During the latter part of the eighteenth century considerable increase of the buildings of the city of Westminster took place. Houses were built along the south side of the road to Knightsbridge, beyond the Green Park, which was now made distinct from St. James's Park; Berkeley Square was formed, in 1720, a street extending from the King's Road and Grosvenor Place and Lower Grosvenor Place, with some of the adjacent parts of Pimlico, were built. These parts were built before 1780; and by the close of the century Bulstrode and many lines of buildings along the Chelsea Road had been erected.

By these successive extensions nearly the whole of the area of the city had been covered with streets and houses. The only considerable space not so occupied, with the exception of the Anglican, was in 1780-5, near Oxford, Westh- ton, Marlborough, Chelseafield, and Devonshire houses, was near the south-western corner of the space comprehended by the boundaries of the city of Westminster. This space partly consisted of the open ground of Tothill Fields, part of the ancient garden of the Knights of St. John of Malbun Place and Edward Street, by William, Ear of Rutland, known as the Five Fields, and other fields between Pimlico and Knightsbridge. During the present century the extension of buildings of various kinds has nearly covered this area. The Five Fields and the fields toward Knightsbridge are now occupied by Belgrave and Eaton squares, and Ebury Street, which form, with their neighbourhood, one of the handsomest quarters of the metropolis: Tothill Fields and the adjoining buildings, are enclosed by the present Millbank Prison or Penitentiary; by Vincent Square, the ample enclosure of which forms the playground of the Westminster scholars; and by various streets adjacent to them. A part of the North-Houses Gardens is still occupied on the north side of the Grosvenor Place, and the park of the Grosvenor Place, which was converted into a canal the 'Grosvenor Canal,' with a basin and wharfs.

Of the population of Westminster until the present century we have no accurate account. It is said by Mr. Rickman, but we know not from what data, to have been about 130,000 at the beginning of the last century. In Middlesex's History of London, the number of houses, at a period, we believe, somewhere about the year 1737, is given at 13,445, which, allowing seven persons to a house, which is an average number, would give an estimate of 94,115 as the number of inhabitants. This estimate and Rickman's cannot be made to agree except by the supposition of a diminution of population in the earlier part of the last century, a supposition which the great increase in the building at that time proves unfounded; or by adopting a higher average of persons to each house, which we are not disposed to admit. We are inclined to think that Rickman's estimate for the beginning of the century is altogether too great, as it would not allow an increase of more than 30,000 during the whole century, which is by no means commensurate with the great increase of the population. In 1811, the population was 108,119, and in 1821, 182,683; in 1831, 226,680.

The municipal government of Westminster was, until the formation, in the hands of the abbot and monks of St. Peter's Abbey. It was finally divided into a deanery and chapter, till 1585, when an act was passed for regulating it. The dean and chapter now appoint a high steward, who holds his office, except in cases of misconduct, for life. The dean and chapter appoint a deputy, who is confirmed by the dean and chapter, and who presides at the court leet and at the quarter-sessions. The dean appoints a high constable, who is confirmed in office by the high steward, and is returning officer at the election of members of parliament. There are several police-offices and courts of requests within the city. A court of record for the liberty of the Duchy of Lancaster is held at Somerset House.

Westminster has had no mayor since the 1st year of Edward VI. Its elections during the latter part of the last century and during the present have, from the extent of the constituency and the vigour of the struggle, usually excited great attention. The number of voters was in the year 1840 it was 14,254, showing a decrease in four years of 1411.

(Camden's Regi6, Regi6n, &c, in Ecclesia B. Patri West- monasteri seuptfi; Cruft's Antiquities of St. Peter's, West- minister; Stow's Survey of London; Maitland's, Hughson's, and Arden's History of London; Brickwood's Westminster, &c. There are several police-offices and courts of requests within the city. A court of record for the liberty of the Duchy of Lancaster is held at Somerset House.

Westminster Assembly of Divines. The principal measures of the Long Parliament, which preceded the dissolution of this assembly, were, briefly stated in the order of time, the following:—

The parliament met on Tuesday, the 3rd of November, 1640. In the front of the grievances about which the Commons immediately began to bear themselves were cases of those relating to religion. The occasion of the first day on which the house entered upon business, Sir Benjamin Rudyards delivered a long speech, which he commenced by observing that they were assembled to do God's business and the king's, and then continued:—Let religion be our primary care; for all things else are but adieteras to it. We well know what disturbance hath been brought upon the church for vain petticoat trife. How the whole church, the whole kingdom hath been troubled where to place a man according to the quality of his ministry, their wives, families, and children undone, equal law, against conscience, against all bowels of compassion, about not dancing on Sundays, and this, belike, is the good work in hand which Dr. Heylin hath so often celebrated in his bold pamphlets. All their actions are so full of mixtures, involutions, and complications, as nothing is clear, nothing sincere in any of their proceedings, They have so brought it to pass that under the name of Puritans all our religion is branded, and the very name is justly accounted the very luxury and countenance. The course subsequently taken by the house was in perfect accordance with the key-note thus struck.

On Monday, the 18th of November, arrived the Commissioners from the nation and army of Scotland, attended by a large staff of chaplains, whose serx?d sermons in St. Anthoni's Church soon added immensely to both the rent and the numbers of the professors of Presbyterianism.
were, however, the citizens of London. The noble commissioners themselves also, who, no more than the preachers, dissembled their desire to see the Covenant the law of both countries, are believed to have been active instigators of many of the measures that the House of Commons then passed. They carried through both without and within the walls of parliament. On Friday, the 20th, a vote was passed by the Commons, 'That at the receiving of the Commonse next Sunday it was the desire of the House that the communion-table may be removed,' and the address of the Lords. On the 11th of December, was presented by Alderman Penuington the famous root-and-branch petition 'from many of his Majesty's subjects in and about the city of London and several counties of the kingdom,' setting forth that the spiritual estates within the city, having proved prejudicial and very dangerous both to the church and commonwealth, and praying that the said government, with all its dependencies, roots, and branches, might be abolished, and the government of the Church of God's word' established in its stead. This petition, which is supposed to have been the contrivance of the Scotch commissioners, is said to have had 15,000 signatures. On the 16th and 18th of December, after the matter had been repeatedly brought in the House of Lords, the Commons agreed to pass the bills for establishing a commission against the powers assumed and the new canons passed by the convocation of the clergy then or lately sitting. Immediately after this commenced the attacks upon Laud, archbishop of Canterbury, and the other bishops. In the meantime, the proceedings of the sub-committee of the Committee of Religion, denominated the 'Committee for Preaching Ministers,' appointed 'to consider how there may be preaching ministers set up where there are none, and how to maintain the present, if the good of the state and of the kingdom, and the worship and service of God,' was brought in, read twice, and committed the same day. On the 10th of March it was resolved 'That the legislative and judicial power of bishops in the House of Peers in parliament is a great hindrance to the purity and due function, prejudicial to the commonwealth, and fit to be taken away by bill; and that a bill be drawn to that purpose.' The next day it was in like manner resolved that a bill should be brought in to prevent bishops or any others by force of the Commons in the commission of the peace, or having any judicial power in the Star-Chamber or in any civil court; and on the 28th, that another bill should be drawn to incapacitate them for being employed as privy-councillors. All these bills were brought in with great celerity, and for advancing the worship and service of God, was brought in, read twice, and committed the same day. On the 10th of March it was resolved 'That the legislative and judicial power of bishops in the House of Peers in parliament is a great hindrance to the purity and due function, prejudicial to the commonwealth, and fit to be taken away by bill; and that a bill be drawn to that purpose.' The next day it was in like manner resolved that a bill should be brought in to prevent bishops or any others by force of the Commons in the commission of the peace, or having any judicial power in the Star-Chamber or in any civil court; and on the 28th, that another bill should be drawn to incapacitate them for being employed as privy-councillors. All these bills were brought in with great celerity, and for advancing the worship and service of God, was brought in, read twice, and committed the same day. On the 10th of March it was resolved 'That the legislative and judicial power of bishops in the House of Peers in parliament is a great hindrance to the purity and due function, prejudicial to the commonwealth, and fit to be taken away by bill; and that a bill be drawn to that purpose.'

Meanwhile, at three o'clock on the morning of the 23rd of November, 1641, after a debate which had lasted twelve hours, the Commons, by a majority of 159 to 148, had passed the famous Remonstrance, or Declaration of the State of the Kingdom, addressed to the king, in which they said: "We believe the nature of the church, that there may be a general synod of the most grave, pious, learned, and judicious divines of this island, assisted with some from foreign parts professing the same religion with us, who may consider of all things mattering to the observances of the church, and represent the results of their consultations unto the parliament, to be there allowed of and confirmed, and receive the stamp of authority, thereby to find passage and obedience throughout the kingdom.' This is, we believe, the first distinctly recorded intimation given by the parliament of their wish to refer the question of religion to a clerical convocation, and it sets forth very explicitly the limits within which they proposed to commit the arrangement of the constitution of the national church, as it was passed, and even before it was presented to the king.

The course of events now proceeded with accelerated rapidity. On the 30th of December, 1641, twelve of the bishops were committed on a charge of high treason for having protested against the validity of any acts of parliament that should pass while the popular tumults around the House of Lords prevented them from taking their seats. On Tuesday, the memorable 4th of January, 1642, Charles struck, ineffectually, his first blow at the parliament by his desperate attempt to seize the five members. On the 10th he rode to Whitehall, and on the 12th, he rode to Westminster with his capital, till he was brought thither a prisoner to be tried and led to execution. On the 22nd of August he erected his standard at Nottingham. On the 1st of September the Commons, and on the 10th the Lords, in London, are the same. Finally, the 30th of November, 1643, there should be no archbishop, bishops, or clergy, of any degree, according to the word of God, to have or lead any church, or of or within any cathedral or collegiate churches in England or Wales; that their names, titles, jurisdictions, offices, and functions should cease, determine, and become absolutely void; that all the manors, lordships, and estates, belonging to any bishop or bishopric should be for the use of the commonwealth, and for the propagation of the spiritual state and service of God; and all their subjects, both town and country, who were subjects of the bishops, to become subjects of the king, or of the crown. On this last occasion the king was not present, but his eldest son, the Duke of York, was with him. This bill was afterwards converted into 'An Ordinance of the Lords and Commons in Parliament,' and passed 23rd June, 1642.

The persons nominated in the ordinance to constitute the assembly consisted of a hundred and twenty-one clergymen, together with ten lords and twenty commoners as lay assessors. Among the commoners were John Selwale, Francis House, Sir Henry Vane, senior and junior, John Glyn (the recorder of London), John Whitelock, Sergeant Wild, Oliver St. John, John Pym, and John Maynard. Among the most distinguished of the clerical members were, Dr. Ralph Brownriggs, bishop of Oxford; Mr. Wentworth (the rector of Saint Peter); Sir Edmund Calamy, Dr. Francis Clarke, Thomas Gataker (the editor of Marcus Antoninus), Thomas Coleman, Thomas Gataker (the editor of Marcus Antoninus), Thomas Goodman, Dr. John Hacket (afterwards bishop of Lichfield), Dr. John Lightfoot, Dr. George Morley (afterwards bishop of Exeter), Lord Wharton (the younger, afterwards bishop of Gloucester), Philip Nye, Dr. John Priest (bishops of Worcester), Dr. Edward Reynolds (afterwards bishop of Norwich), Dr. Robert Saunders (afterwards bishop of Lincoln), Dr. James Usher (archbishop of Armagh), George Walker, Dr. Samwel Ward, Dr. James Wallis (the mathematician). Several other persons (about twenty in all) were appointed by the parliament from time to time to supply vacancies occasioned by death, secession, or otherwise, who were called superadded divines. Finally, two lay assessors, John Lord Milton and Sir Abraham Johnson of Warrington, and four ministers, Alexander Ben-
The Assembly of Divines had been forbidden by the king in a proclamation dated the 22nd of June. The only effect however of that prohibition had been to induce the greater number of the members of episcopal principles to refrain from attending. On Saturday, the 29th of June, sixty-nine clerical members assembled in Henry the Seventh's chapel, in Westminster Abbey. They appeared, as it is recorded, not in their canonical habilis, but mostly, after the fashion of foreign Protestant clergy, in black caps. The presence of so many persons appeared to have ranged between sixty and eighty. About twenty-five of the persons who had been nominated members of the Assembly (including one or two who had died) were present in their seats; and even of the sixty or seventy who attended irregularly, only from twelve to twenty were frequent speakers.

In theological doctrine the divines of the Westminster Assembly were almost to a man of one mind. They were all, or nearly all, Calvinists. Their Shorter Catechism was drawn up by Burroughs and others, and having been adopted by a unanimous vote of that body on the 17th of August, was then forwarded to the English parliament and the Assembly of Divines at Westminster for their consideration.

The Second of October, 1647, the Assembly of Divines commenced its proceedings, and the Assembly of Committee of both houses, having been twice attended with a sufficient number of members to transact business, again assembled together. The house of commons, however, was not present. The preamble was laid on the table, and the committee proceeded to the consideration of the same. The reading of the preamble was long and tedious. The committee proceeded to the consideration of the same.
The only work that has appeared professing to be a History of the Westminster Assembly of Divines is a 12mo. work, intitled 'Preface to the Life of the Late Rev. Mr. Hetherington, then minister of Torphichen, published at Edinburgh in the present year, 1843. The reader is referred for a further account of the sources of information on the subject to Mr. Hetherington's Preface, and to a note on p. 90 of 'Atton's Life and Times of Alexander Henderson,' 8vo., Edinburgh, 1836.

WESTMORELAND, or WESTMORLAND, a northern county of England, bounded on the north and north-western side by the county of Cumberland; on the north-eastern side, it is separated by Ullswater Lake, by the river Eamont, which flows from Ullswater into the Eden, by the Eden itself, and by the Crowndale, another feeder of the Eden: on the south-west it is bounded by the district of Furness in Lancashire, from which it is separated in one part by Little Langdale Beck, Elter Water, and the Brathay, a stream flowing into the lake of Windermere, or Winandermere, and by the western shore of Windermere itself; the boundary-line then passes round the foot of the lake, up its eastern shore to its head, and ascends in an easterly direction to the head of the little river Wincer, which separates Westmorland and Lancashire during its whole course to its junction with the estuary of the Ken, or Kent, just where it opens into Morecambe Bay; or the county is bounded by the south-east, east, and north-east by Yorkshire, from which, in different parts, it is separated by the river Lune and its feeder the Rather, by the upper part of the Eden, or its feeder the Matt, following the line of that river for a short distance on the north-east it is bounded by the county of Durham, from which it is separated throughout by the upper course of the Tees. It lies between 54° 10' and 54° 42' N. lat., and between 2° 9' and 3° 10' W. long.

The name of the county is derived from the greatest direction or length is from north-east to south-west, from the division of the three counties of Cumberland, Westmoreland, and Durham, on the bank of the Tees, to the junction of Westmorland and Lancashire, on the shore of the Kent, a little way from the mouth of the Kent, more than 41 miles: the greatest breadth, measured at right angles to the length, is from Bowfell, on the border of Cumberland, to the county stone at the junction of the three counties, Yorkshire, Lancashire, and Westmorland, 39 miles. The area of the county is estimated at 765 square miles; the aggregate areas of the several parishes are estimated at 485,990 acres, or rather more than 759 square miles; the population by the different enumerations of the present century was as follows: in 1801, 43,411; in 1811, 45,922; in ten years 10 per cent. 1821, 51,350; increase 12 per cent. 1831, 55,041; increase 7 per cent. 1841, 56,469; increase 2½ per cent. It is in area the twenty-ninth of English counties; in amount of population (excluding the town) the thirty-first of the year 1831, and it is criss-crossed by roads, with an auxiliary number, to facilitate comparison, the thirty-eighth, being exceeded by all others, except Huntingdonshire and Rutlandshire; and in density of population by far the lowest of all, has only 72 inhabitants to a square mile; Cumberland, the county in this respect next above it, having 111 persons to a square mile. By the census of 1841, Westmoreland was surpassed in population by Huntingdonshire. Appleby, the county town, is in the northern part of the county, in 54° 34' or 54° 33' N. lat. and 2° 29' W. long., 231 miles in a straight line from London; 2704 miles by the road through Barnet, Hatfield, Bignoleswood, Norman Cross, Stamford, Newark, East Retford, Doncaster, Aberford, Boroughbridge, Catterick, Greas Bridge, and Brough; or 280 miles by the Northern line. From Preston and Lancaster railways to Lancaster, and thence by coach-road through Kendal and Shap.

Surface and Geography.—Westmoreland is wholly mountainous, save the eastern side and the centre are occupied by the mountains of the Cumbrian group, which are separated from the Pennine Chain by the valley of the Eden. The principal ridge of the Pennine Chain enters the county close to the northern border just to the south of Cross Fell, and extends across Millburn Forest south-south-east by Brough to the border of Yorkshire in Arkengarth Forest; it then turns south-south-west, and runs, above Kirby Stephen, to the head of the valley of the Eden. On the west side of this ridge the mountains have a steep and almost precipitous descent into the valley of the Eden; on the east, they consist of a broad range, bounded by the boundaries of Westmoreland, subsiding more gradually into the wide valley or plain of the Tees, which occupies the south-east of the county of Durham and the north of Yorkshire. On each side of the ridge a number of transverse valleys are drained by small streams: those on the west side flowing into the Eden; those on the east forming the upper waters of the Tees, the Swale, and the Ure or Yore. The principal mountains of the Pennine Chain in Westmoreland are: Shap Fell (flanked on the west by Dunron Pike and Knock Pike), Eagles' Chare, Scordale Head (flanked on the south-west by Murton Pike), Warcop Fell (which is flanked by Little Fell on the east and Roman Fell on the west), Middle Fell, Missgram Fell, and Helbeck Fell, all northern part of the depression, through which the river below passes. South of that depression are a number of summits grouped together, and forming the district of Arkengarth Forest, of which the Nine Standards (2136 feet high), Dowphin Seat, Browner Bell, and Hugh's Seat, the greatest border of Westmoreland and Yorkshire, are among the principal. The northern part of the Pennine Chain is in Millburn or Milburn Forest: the part near the bend where the range turns to the south-south-west is in Arkengarth Forest, which some make to a part of Lancashire and others of Yorkshire, and the southern part is in Swaledale Forest and Mallerstang Forest.

The principal ridge of the Cumbrian Mountains crosses the county from west to east, or, more accurately, it reaches the highest point of the group, 3555 feet high, Storr's Chain, between Patterdale, Parton, and Kirkby Stephen, which, from the head of the valley of the Eden, on the eastern side of the county: by which valley, here very narrow, it is separated from the Pennine Chain. It may indeed be considered as united at the head of the valley of the Eden, in Mallerstang Forest, whose part of the county is in Northumberland, and that of the Kent, the part of the county of Eastmoreland, or Kirkstone Fell and the valley of the Eden is divided into two parts by a depression through which the Lune passes. The principal mountains along the ridge are Grisdale Brow (1982 feet high) and Dow Craggs, between Helvellyn and Kirkstone Fell; High Street, 2551 feet, the highest point of Kentmere; Birkbeck Falls and Hause Hill, near the head of Borrowdale; Jeffery's Mount, on the west side of the depression through which the Lune flows; Langdale Falls, the head of the Langdale Valley; Great Langdale Fell, near the head of the Lune; and Wild-Boar Fell, in Mallerstang Forest, near the west side of the valley of the Eden. From each side of the ridge ramifications are thrown off, extending northward to the border of Cumberland, and southward to the border of Lancashire, or the shore of Morecambe Bay.

On the north side a principal branch is thrown off from the main ridge at High Street, a short distance east of Kirkstone Fell, of which branch Dodd Hill, Place Fell, Aldsray Pike, Kiddy Pike, the peaks in Martindale Forest, and Swareth Fell are summits. This branch extends nearly to the bank of the Eamont, a principal feeder of the Eden, opposite Penthall; and forms, with that part of the main ridge which is between Helvellyn and Kirkstone Fell, a somewhat precipitous ascent to Kirkstone Fell and High Street, a semicircle, having the upper part of the lake of Ullswater embosomed in its centre. This lake, the upper part of which belongs wholly to Westmoreland, with the lower part is on the border of Cumberland and Westmoreland, and is bounded, with an average breadth of half a mile. Hodgson's 'County Survey' however runs the boundary-line of the two counties upon the centre of the lake from Glencoa to Glencoin, the great head of Ullswater, at the boundary of Patterdale, into which open other dales or valleys, including Glencoen or Glencoin, Glenriddin, Grisdale, and Deepdale, which are formed by the short branches thrown off towards the lake by the semicircle of mountains which lie surrounded by Martindale above the northern end upon the south-east side of Ullswater; it lies between the hills of Martindale Forest on the east, and a detached mountain or hill on the west. These dales are watered by mountain streams flowing into Ullswater.
Then* the Green-Slate flows.

From the main ridge near Birbeck Fells an important branch is thrown off in a north-east direction; but between this and the branch ridge, which has been described as parting from the main ridge at High Street, are two shorter branches separated from the High Street branch by the valley of Mardale; from each other by the valley of Swithland, and from the valley of Great Langdale by the valleys of Little Langdale and the Little Lode, Drunken Gill, and Wet Sledscale. These three valleys are drained by three streams which unite to form the Lowther, a feeder of the Kentmont.

The westernmost, flowing through Mardale, expands into a wide vale, and from each of these valleys, from an eastern quarter to half a mile wide. The stream which waters Wet Sledscale is the most considerable of the three.

The branch from the principal ridge of the mountains at Birbeck Fells is known in the part nearest the ridge as the Great Fells. It extends northward in several ridges separated by intervening vales, Knife Scar, and the hillside of Shap Moor, Newby High Moor, Ravensworth and Meaburn Moors, and Colby Common, all belong to this branch.

The intervening vales have a general direction north and south, and are connected by the flow of a small stream which joins the Eden between Kirkby Thoresby and Temple Sowerby. Part of the hills which form this branch, including Oddendale Knab, Orton Scar, Asby Moor, Crudby Fell, Ash Fell, and Birk Fell, extend eastward in a direction parallel to the main ridge, from which they are separated by a valley watered by the Lune and its upper affluent.

The branches from the main ridge on the south side extend on the western side of the county into the county of Lancashire, and into the valley of the Ribble, and other small streams. All the branches are cut by the valleys draining the valley of Grasmere, by which they are separated from a detached group of the Cumbrian Mountains, which occupies the western extremity of the county. These branches and valleys extend Long Sleddale, and are separated from Grasmere and drained by streams which flow into the upper part of Windermere. A branch somewhat longer than those just described extends between Ambleside and the Troutbeck to the shores of Windermere. Another branch is more eastern, and joins the ridge northward in the valley of the Kent, being drained by the east Kentdale and the valley of the Kent, and on the west by Windermere and the valley of the Lune. Near the ridge the country is more not much breadth, and as it advances southward it becomes broader, and is subdivided by the valleys drained by the Whinter, the Witherslack brook, the Underbarrow, and other small streams, into parallel ranges of hills and valleys, called the Kentdale, Pooleyeshire, and Withbarrow Scar, Lyth Fell, and Underbarrow Scar in Westmoreland.

Other branches from the main ridge, subdivided, like that just mentioned, into parallel ranges of hills, spread over that part of the county which lies between the Kent and the Lune. Of these branches one part, including the hills of Sledscale Forest and Potter Fell, separates from the ridge near Harker Fell, and extends between the valley of Kentmere, watered by the upper course of the Kent, and the valley of the Lune, and is watered by the Sprey, a feeder of the Kent, southward to the junction of this feeder with its principal. Another part, of which Crow Brow and Tod Fell form part, extends southward on the east side of Long Sleddale, which it separates from another valley to the south, which are separated by the Great Fells, and which joins the Kent just above Kendal. Other parts of this branch, comprehending the heights of Whinfell Common and Lambright Park, Hay Fell, Rowland Edge, and, more to the southward, Haverbruck Fell, Arnsdale Fell, and Great Shap, extend southward between the Kent and the Lune into Lancashire; the parallel ranges of hills being separated by streams which join the Beelo, a feeder of the Kent. That part of the county which extends across the Lune westward is occupied by Middleton Fell, Barbon Fell, Barbon Beacon, Great Colm, Bowena, and Casterton Fell, all belonging to the group which separates Dentdale in Yorkshire from the lower part of Lonsdale, or the valley of the Lune, in Westmoreland and Lancashire.

The western extremity of the county is occupied by part of another group of the Cumbrian Mountains, separated from that part of the principal ridge which is between Helvellyn and Kirkstone Fell, by the valley of Grasmere; and from the Furness Fells of Lancashire by the valley of Little Langdale, and divided into two parts by the valley of Great Langdale.

Lancashire. Here they are watered by the Lune and Loughrigg Fells are between Grasmere and Great Langdale; and Bow Fell (2111 feet high), on the border of Westmoreland and Cumberland, and Wrynose, or Wrynee, form the western termination of the valleys of Great Langdale and Little Langdale unite in the tarn or group of Eter Water, which flows into the Loughrigg tarn, adjacent to the south foot of Loughrigg Fell, so forming the Brathay; the stream which waters Grasmere receives streams from two tarns in the upper part of the valley, expands in the lower part of the valley into two lakes of Grasmere and Rydal Water, and thence into the Windermere, forming the Rothay, which, with the Brathay just named, form the principal feeders of that lake.

Geologically the county may be regarded as consisting of three parts. The slate rocks of the Cumbrian Mountain division are separated by the great carboniferous and mountain limestone series of the North of England, of which formations the Pennine Chain forms the western outcrop, constitutes the second part or division; and the new red-sandstone of the valley of the Kent, the third.

If a line be drawn in a south-easterly direction from the foot of Uluzzlewath, passing a little to the south-west of Shap and Orton, and thence to Ravenstonedale, at that place bending to the south coast of the county, at a point where the road from Sedbergh to Kirkby Stephen enters it; and another line be drawn nearly at right angles to the former, commencing at Shap Wells, passing by the south side of Wansfell Crags, and crossing the valley of the Kent, the western part of the county of Kentmere near the Hall, and the valley of Troutbeck a little above Town Head, and thence, skirting the southern flank of Wansfell, to Pool Wyke, near the north-west angle of Windermere;—the whole county will be divided into three irregular and unconnected districts, each marked by peculiar geological features. We shall consider them in the following order:

1. The green-slate and porphyry of the north-western district.

2. The upper slates of the south-east.

3. The carboniferous rocks of the north-east, and the new red-sandstone of the basin of the Eden.

1. Green-Slate and Porphyry.—This, the middle term of the series into which the rocks of the county have been divided, and overlapping the lowest member of that series in the adjoining county (the Skiddaw Slate of Sedgwick) occupies the whole of the north-western portion of the county, and is bounded on the south by the range of a series of overlying beds of calcareous slates (Coulston limestone &c.), and on the north-east by the carboniferous rocks. It comprehends two distinct classes of rock, igneous and aqueous, yet so blended and intermixed that they must be considered as the effects of two distinct causes acting together and continuing during a lengthened geological period. The igneous rocks include almost every variety of felsite and felsinite-porphyry, occasionally pass into greenstone; they more rarely put on a columnar form like that of basalts, and occasionally resemble rocks of the hornblende or Main group. But these rocks are so cut up, and are so extensively at the state of commination, and obtain their typical colour from earthy chlorite derived from the Plutonic sills. All these rocks have, in a greater or less degree, a columnar structure, and from the finest rock-slates to the coarsest granite, and from the highest and most rugged peaks of the whole lake district, constituting the main ridge of the mountains west of High Street, to the intervening valleys of Grasmere and Great Langdale, &c. In the valley between Grasmere and Great Langdale, &c. and the tilt of the rocks is north-east, and they dip at a steep angle of the rocks is the southern end. Garnets are found in some abundance in these rocks, and they are so abundant in the brecciated rocks of this district that the lastly discovered in any part.

No organic remains have been discovered in any part of the group, the internal composition of the rocks. These rocks have been so frequent to permit the extraction of any organic remains from them.
life. Metallic veins occur in some places; amongst others, a lead-niue is worked south-west of Ulleswater.

2. The South-Eastern District.—This formation is divided by Professor Sedgwick (see "Proceedings of GeoL. Soc., Lon.," 1832) into three ill-defined groups: 1. the fossiliferous rocks south of Kendal and of Kirkby Moor; 2. a lower group, lying east of the scar in limestones and grits; but with a more decided slatey impress and fewer traces of fossils; 3. a complicated group of calcareous slates, alternating with hard coarse siliceous beds and several bands of fine roofing-slates, all resting on the fossiliferous rocks of Coniston. A recent survey of this district, also separates this division of the slate rocks into three groups (see "Proceedings of GeoL. Soc., Lon.," 1843), and seeks to identify them with the three principal groups of Mr. Murchison's Silurian System. Mr. Sharpe's division will involve a descending order of making a traverse from the south-east to the north-west; as, for instance, from Kirkby Lonsdale, where the uppermost beds underlie the old red-sandstone, to the Coniston limestone above Low Wood, at the head of Windermere, first, Upper Ludlow rocks, occupying the greater part of the district between the lower parts of the Kent and Lune, succeeded by a band of Lower Ludlow rocks; next, a series of unfossiliferous beds (of considerable thickness when expanded) underlies the district of Windermere rocks, and are the assumed equivalents of the Wenlock formation; and, lastly, a series of slates (Kirkby Ireleth, grey slaty grits, blue flagstones, and Coniston limestone—the last being the supposed equivalents of the Cardoc sandstone). The Coniston limestone forms a well-defined though irregular base to this division of the slates on the north-west (this boundary being rudely marked by the line we supposed to be drawn from Shap to Highmilestone, and thence to Ulleswater). On the south and south-east it is bounded by Morecambe Bay and the carboniferous rocks, and it extends eastward as far as the border of the county, except where overlaid by the carboniferous series of Yorkshire. Three banks are observable on the eastern side of the Lune, all of which are separated by the western bank of an enormous fault, which ranges in the direction of that river. Middleton and the other Fells on the eastern side of the Lune are composed of the beds of the middle group of this division. The exact age of this upper division of the slates can only be ascertained by an appeal to the organic remains, which are sufficiently abundant in the first and uppermost, and in the third or lower terms of the series. The rocks to the east of Kendal and those which break through the western Carboniferous limestone of Underbarrow Scar abound with Upper Silurian fossils, and the Coniston limestone is charged with Lower Silurian crustacean shells and corals. The middle term is fortunately without organic remains and is in the absence of the other bank. (Aynsley and Wenlock limestones). Professor Sedgwick's recommendation to separate the whole upper division of the slates of Westmorland into two groups, an upper and a lower, seems to be at the safest plan. These uppermost slates are harder than those of the lowest series and, give to the mountains formed of them a more angular and picturesque outline and rugged surface; but they do not in these respects equal the middle series of slate rocks, which form mountains of greater elevation. The more piquant mountains formed by the uppermost slates rarely have a height of 1000 feet, being inferior not only to the middle slate mountains (Helvellyn, Langdale Pikes, etc.), but also to the limestone mountains of the Pennine Chain. Among the Slates of the south-western summits there are several parallel line of greenstone. This small slate and greenstone district is distinguished by three lofty conical summits or 'pikes': Knock Pike, the most northerly, is chiefly composed of greenstone; Dufton Pike, which, near to, and contains both greenstone and slate, and Miron Pike, the south-westernmost, appears to be almost entirely composed of slate. The line of junction and order of superposition of the greenstone slate, if they have any order, have not been determined. Streaks of greenstone are found on Langdon Moor, near Merton Pike, and at Middle Rigg; and slate rocks are obtained in several places. Granite rocks are found in this district, and a species of granite used for fencen is quarried near Dunton Pike. Shattered and confused portions of the coal-measures and of the mountain slates are observed to be of the greenstone on the west for about three miles between Melford and Kirkland. The coal-seams, which are very thin, are often quite vertical, and the coal has been extracted by sinking perpendicularly with a few horizontal characteristics from the mine; without any clue to lead to their recovery, the coal is now seldom worked.

The millstone-grit is seen only on the eastern border of the county, covering the mountain limestone and forming the bed of Dunton Fell, which is composed of a fine uniform limestone. The limestone beds are seen in two parallel lines of greenstone. The beds are thick at the eastern end and thin near the middle of the Cumbrian Mountains. These coal-pits are found at the junction of millstone-grit between Appleby and Shap there are several coal-pits. This small coalfield is covered by a national dyke. There are some coal-pits at Holbeck near Brathay. On the southern side of the county the carboniferous limestone appears broken up by enormous faults into detached portions with wide valleys between them; one large mass, with several outliers, commences about two
miles north of Kendal, and extend as far south as the shores of Morecambe Bay, resting on the Silurian rocks, which underliemost of the land. Here and there the old red-sandstone (Plumgarths, Lonsdale, Birkbeck, Slate Hill) makes its long south-western escarpment of Underbarrow Scar is another mass of limestone (Whitbarrow). The limestone at Kendal is extensively quarried for building purposes, and much of the material obtained from it is shipped eastwards, to the east of the town being much in demand for ornamental purposes. Another mass of limestone of some extent lies to the south-west of Kirkby Lonsdale.

The new red-sandstone is the most recent formation of the Cumbrian Mountains, it fills all the lower part of the Eden, from near Brough to the shores of the Solway Firth. It usually appears here as a strong thick-bedded sandstone, and is much used as a building-stone. It rests upon the carboniferous rocks on its south-western side, and, spreading wide on both sides of the Eden, abuts against the upraised terrace of Cross Fell elevated by the great Pennine fault. Immense masses of magnesian conglomerate may be seen at the bed of the Eden near Kirkby Stephen, containing water-worn and unabraded fragments of the mountain limestone and coal-measures; the gypsum is obtained in many parts of the saliferous district in Westmorland.

Proofs of igneous action are abundant in many parts of this county; porphyritic dykes being found in various parts; the sandstone itself is not very distant from the 'Shap Granite' in Wet Sleddale, in the valley above High Barrow Bridge, on the crest of the hill from that place to Shap, and in two places farther north and near the road-side. But the well-known Shap Fell red sandstone, which runs for several miles long the length of the hill on the rock in the county. It rises at the base of the upper division of the slates, and appears to have cut off the Coniston limestone for some distance; altering, tilting off at high angles, and indurating all the neighbouring rocks. The boulder-clay at this granite and the Kampermuck may be found to have travelled in one direction as far as the Yorkshire coast. They are seen resting at the height of several hundred feet above the level of the plain of Eden, against the steep sides of the great ridge of Cross Fell, and they bear witness to the sudden elevation of that range.

The mode of their transport, whether by water, or by ice, or by ice floating in water, is yet an unsolved problem in geological dynamics.

Hydrography and Communications. — The Pennine chain of mountains separates the watersheds which flow into the Irish Sea from those which flow into the German Ocean. Westmorland is chiefly on the western side of the chain; but a small portion is on the eastern side of the ridge, and in some parts of the upper waters of the Tees has a direct outlet to the sea. The Tees divides the northern boundary of Cross Fell, but its course as far as the fall at Cauldron Snout is on the border of Westmorland. Near the mouth of the Tees in the north-eastern part of the county, and having its course within or upon the Eden. The sources of the Lune or Lune (which must not be confounded with the Lune described below), the Bauder or Baulder, the Greta, and its affluent the Barney, all belonging to the system of the Tees, are within or upon the border of Westmorland. The Swale, which belongs to the system of the Ouse, has also its source on the border. But all these streams, which belong to the eastern slope of the Pennine Chain, have scarcely anything in common with the streams of Westmorland, that chain which determines the watershed lies very near if not close upon the eastern border of the county. Of the Tees about eight or ten miles belong to this county; the length of the Maise, which belongs wholly to it, is about the same. Of the Lune the whole of the county belongs to it; but of the other rivers scarcely more than a mile or two.

On the western side of the Pennine Chain the county is divided by the principal tributaries of the Cumbrian chain into two basins: the basin of the Eden on the north, and the basin of Morecambe Bay on the south, drained by theKent, the Lune, and other streams, which flow into that estuary. The Eden rises on the border of Westmorland and Yorkshire, on the side of Hugh's Seat, one of the mountain tops of the Pennine Chain. Its course for the first two miles is southward; then it abruptly turns to the north, and flows northward through four miles through a narrow valley en-closed between the Pennine and Cumbrian Mountains past Kirkby Stephen to about a mile from the village of Souley, where it receives on the left bank a stream eight miles long, which rises in the Cumbrian Chain near Dun Fell, and has a course of seven miles west-south-west along the border of Westmorland and Cumberland into the Eden, which it joins on the right. From the junction of the Crowndundale the Eden flows two miles more north-west, along the border of the county to the junction of the Emmont on the left bank, after which it quits Westmoreland altogether. Its course in this county is 30 miles; in Cumberland about the same; making a total of nearly 60 miles. No part of its course in Westmoreland is navigable.

Below the stream which joins it at Souley, the Eden receives several other affluents. Those which join it on the right bank are the Beech or Belay, seven or eight miles long, which wavers St. formed by Stanemore Dale; the Hillbeck, a stream six miles long, which passes the town of Brough; the Troutbeck, ten miles long, which rises near Scordale head; and the Crowndundale, already noticed: all these rise in the Pennine Chain. On the left bank of the Eden is joined by the stream which falls from Ashby; a stream seven miles long from Great Ashby; by a third stream, the Leech, eleven miles long, from the neighbourhood of Shap (which last receives the Lyvennet, the Troutbeck, and the Crowndundale), and the Emmont, from Uleswater, on the border of the county.

The Coldell or Hartop beck, which rises in the Cumbrian ridge at the foot of Kirkstone, may be regarded as the true source of the Emmont: it flows into Uleswater at its upper end, and passes by the same fell in Mallerstang, to the lower end: the course of the Emmont is north-east along the border of Cumberland and Westmorland: its total length from the source of the Coldell, including Uleswater, which is an expansion of it, is about 20 to 22 miles. About four miles below its source it joins the river Eden. The Lotherside, formed by the junction of three becks or streams, which respectively water Wet Sleddale, Swindale, and Mardale: the length of the Lowther from the head of the Wet Sleddale beck, the longest of the three, is more than 16 miles, which wavers St. formed by Uldale Dale; the Mardale beck. All the larger affluents of the Eden which join it on the left bank rise on the northern slope of the Cumbrian ridge.

The Lune, the Kent, the Winster, and the Leven drain the basin of Morecambe Bay. The Lune rises on the northern side of the Cumbrian ridge near the head of the stream, which joins the Eden at Souley. Its course is northward for two miles, then westward for six miles through the plain of Eden near Kirkby Lonsdale, turns south and the eastward prolongation of the branch thrown off from the main ridge at Birkbeck and Shap Fells on the north. The affluents of the Lune in this part are all small. A little south of Orton the river turns south, and flows 19 miles southwards partly in the county, partly on the border, to Kirkby Lonsdale, a little below which it quits the county to enter Lancashire. No part of its course of 27 miles in Westmorland is navigable. Its tributary the Rither or Roatha rises in Westmorland, then turns to the north and joins the river at its source on the border of Yorkshire and Westmorland.

The Kent rises at the foot of High Street in the Cumbrian ridge, and flows south by east about 10 miles through the valley of Kentdale to the junction of the Sprint Burn at Burneside, a stream of nearly equal length which rises in the same ridge east of the Kent and drains the valley of Long Sleddale. This river joins the Kent on the left bank; and about a mile lower down the Kent receives on the right bank the foot of the river Mint, which is 60 miles long, which drains the valleys of Bannisdale and Whinfell. From the junction of the Mint, the Kent flows 12 miles southward by the town of Kendal into Morecambe Bay. Its whole course of 23 miles belongs to the county, and it is navigable to the head of its estuary. There is no navigable reach on the right bank the Pool, formed by the junction of the Underbarrow and another stream; and on the left the Beet, or...
parallel to the Kent, and joins that river by a sudden bend to the west near Beatham. The length of the Pool with the Underbarrow is about 9 miles; of the Beelo 14 miles.

The Winter, also called the Pool, rises in Westmoreland, and flows some 10 miles, along the broad valley of Furness in Lancaster into Morecambe Bay. The Leven, which flows out of Windermere, belongs to Lancashire; but the Rothay or Raisebeck, which drains the valley of Grasmere, the streams which drain the valleys of Great Langdale, Little Langdale, and the Troutbeck, which all flow into Windermere, and may be regarded as the upper waters of the Leven, belong to Westmoreland. Eaterwater, Grasmere, Rydal Water, and some other small lakes or tarns, are connected with the streams which flow into Windermere. Ullswater and Haweswater have been given in speaking of the mountains, and the position of others has been noticed. Though Windermere has been described under Lancashire as situated in the county, yet in Hodgson's 'County Survey' it is included in Westmoreland; and the Court Rolls at Lowther Castle describe the fisheries (which comprise all the lake) as held under the barony of Kendal by the payment of certain lord's rents, and they are also rated in that county. For economical or commercial purposes the rivers and lakes of Westmoreland are of little importance; but in combination with the rugged mountains and the secluded valleys amid which they are found, they give to the county a high degree of beauty. The first impression of the lakes, says Wordsworth, in his 'Scenery of the Lakes,' is endlessly diversified, sweeping easily or boldly in simple majesty, abrupt and precipitous, or soft and elegant. In magnitude and grandeur they are individually inferior to the lakes in the west of England; with some exceptions parts of this island; but in the combinations which they make, towering above each other, or lifting themselves in ridges like the waves of a tumultuous sea, and in the beauty and variety of their outlines, they are unsurpassed by any.

The mountains are generally covered with turf, rendered rich and green by the moisture of the climate; forming in some places an unbroken extent of pasture, in others laid partially bare by torrents and burnings of water from the mountains in heavy rain. Windermere, is not the only lake, want of timber-trees is particularly felt, but coppices are tolerably numerous. The trees are chiefly oak, ash, birch, and a few elms, with underwood of hazel, holly, and white and black thorns. Scotch fir, beeches, larches, and limes have been introduced. Cultivation, by means of terraces, is constantly found on the mountains; heath and furze are found only in places.

The valleys are for the most part winding, and in many they are abrupt and intricate; the bottom of the valleys is for the most part flat and level, in places spacious gently declining area, level as the surface of a lake except where broken by rocks and hills that rise up like so many islands from the plain.

These lakes, as compared with those of Switzerland and even of Scotland, is favourable to the production of variegated landscapes, and their boundary-lines are either gracefully or boldly indented: in some parts rugged steeps, admitting of no cultivation, descend into the water; in others, gently sloping lawns and rich woods, or flat and fertile meadows stretch between the margin of the lake and the mountains. The margin of the lakes is generally lined either with a fine bushy gravel thrown up by the water, or with patches of reeds and bulrushes, while the surface of the plain, the low plain, the wide and extensive plain, the Loughrigg Tarn, near the junction of the valleys of Great and Little Langdale, is one of the most beautiful. The mountain tarns are difficult of access, and naked, desolate, and gloomy, yet impressive from these very characteristics.

The streams of Westmoreland are rather large brooks than rivers, with very limpid water, allowing their rocky or gravelly beds to be seen to a great depth. The number of torrents and smaller brooks, with their waterfalls and waterbreaks or rapids, is very great. The wide estuary of the Kent presents at low-water a vast expanse of sand, with a shallow bed of mussels, oysters, and fish, as trout, eel, bass, perch, tench, roach, pike, char, and others. Sea-fish are also abundant on the shore of Morecambe Bay.

The principal coach-roads in the county are the mail-roads from Lancaster (to which the mails are sent from London by railway), to Carlisle and Glasgow; and the road (formerly a mail-road) through Stamford, Newark, Doncaster, and Greta Bridge, to Carlisle and Glasgow. The Carlisle mail-road enters the county on the south-west, and Kwente near Ulleswater; and runs north-west by Kendal, Shap, and Brougham, to Penrith; before reaching the last-mentioned town it crosses the Eskmont into Cumberland. The road by Newark and Greta Bridge to Carlisle enters the county on the eastern side near the head of the Greta and of the Beeth, and runs north-westward by Brough, and Bondgate, a suburb of Appleby, to Brougham, where it joins the road just described. There is a second road from Lancaster to Kendal, through Milnthorpe, crossing the Kent, in a line interesting to picturesque lovers from Kendal south-westward to Ulverstone and Dalton-in-Furness; westward to Bowness and across Windermere by the ferry to Haweswater, and Coniston-Water in Furness, and to Egremont and Whitehaven in Cumberland; north-westward by Keswick and Newlands to Keswick, and south-eastward by Kirkby Lonsdale to Settle, Skipton, Otley, and Leeds.

Westmoreland has no railways, and only one canal, the Lancaster Canal, the first act for which was obtained in 1762. This canal, commenced at Lancaster, at a height of 144 feet above the level of the sea, and runs southward with some bends by Burton in Kendal to Lancaster and Preston in Lancashire. Near Burton in Kendal it has a descent of 94 feet by eight locks. The canal passes through a tunnel 310 yards long. There is a canal 5 or 6 miles south of Kendal, and is carried by an aqueduct bridge over the Beelo near Milnthorpe. About twelve miles of the canal are in Westmoreland.

Agriculture—Although this county, from its mountainous nature, is less interesting ecologically than in an agricultural point of view, it contains some very fertile valleys, in which there are as many well-cultivated farms. The climate is mild and moist in the valleys: the high hills condense the clouds which come over the Atlantic, and cause them to fall in abundant quantities on the mountains, which are green, but are not so favourable to the ripening of the corn. Much snow often accumulates in winter. The greater part of the surface of this county, which is reckoned to contain 475,000 acres, is divided into small meadows, pastures or for plantations of timber-trees. Dr. Watson, late bishop of Llandaff, who was a native of this county, took much interest in the increase of woods, and made many calculations on the profits of planting, which appeared to offer great advantages to those who would engage in this speculation, and he showed a good example by making extensive plantations on the sides of barren hills which he had purchased.

The soil in the valleys is mostly a dry gravelly mould, composed of stones, ashes. The waters are washed down from the hills, and forming a soil well fitted for the cultivation of turnips, of which great crops are raised on some well-managed farms. Towards the east and north of the county the soil is more improved to the extent of the areas of the fields, the land is too wet, in spring and autumn, to admit of clean and careful cultivation. Wherever the water has no sufficient outlet, basins of peat are formed; but these are not so extensive as they are in many other hilly counties. These small circular basins, which are the summit of a great part of the hills, and which, being porous, prevent the accumulation of water, except in those parts where they form the lakes which make this county so interesting to travellers.

There was formerly a great many small proprietors in Westmoreland who were called Statemen, that is, Estatesmen—men who held land of their own, either to
freehold, or by a customary tenure, somewhat resembling copyhold, under some great landlord. With the exception of a fine or heriot on the death of a tenant or on alienation, they were held free. The proprietors of these very small farms were an independent set of men, who worked hard and lived frugally. They understood the trade of weaving, and were a good farmer in his wish to improve the cultivation. It is to be hoped that more liberal views may yet be taken by the present agents and proprietors, and a greater scope given to improvements. Draining the heavy lands has been the chief object of attention; and in no county is it more beneficial than in this, where the rains are so abundant, that the evaporation from the surface of the soil can never keep it in a dry state, if the subsoil is retentive of moisture.

The principles of husbandry were originally very simple and not of the most improved forms, but increased communication by means of good roads, and the influx of visitors attracted by the beauty of the scenery, have contributed much to introduce every improvement on those farming lands and on the heath and moors. The land is occupied by tenants who have sufficient capital. These however are not so numerous as it were to be desired for the improvement of the farms. A considerable portion of every farm is generally worked by the owner, who wishes, and is fit for milk cows, moderate on the slope of the hills, and only on the mountains: some rough cattle are reared and many mountain sheep feed on the hills. These often suffer much from the severity of the winter; but as they cost little to keep, they are not much attended to; and in no county is it more beneficial than in this, where the rains are so abundant, that the evaporation from the surface of the soil can never keep it in a dry state.

The old system of cultivation was very simple: when the pastures became mossy, owing to the wetness of the climate, they were ploughed up; one or two crops of oats were raised, and the land remained in grass. Oats and barley, then oats again, when the land was left to run to grass, which it did in about three years. It remained in pasture for five or six years longer, when it became mossy again, and was again broken up and ploughed as before. In every farm there are many a small mound, and the common land is fenced off, but by the introduction of turnips and clover in the rotation the land has been made to produce a much greater return, while it has been gradually improved; and by sowing good grass-seeds the produce has been much increased in quality, while the herbage is more free from natural weeds.

From Kirkby Stephen to Brough and Appleby and thence to Temple Sowerby the soil is a deep sand, which in a dry country would be very unproductive; but which the moisture of the climate renders most productive in the compact on cultivation. Turnips and potatoes grow well here, when plenty of manure is put on. Lime is a great improver of this soil, and fortunately abounds in the county. Near Kendal a great breadth of potatoes is planted for the supply not only of the immediate neighbourhood, but also of the adjacent counties, and of thousands of acres being annually sent into Lancashire and Yorkshire.

The heavy lands were generally cultivated on the old system of wearing; the crops were grown on and some of the manure raised from the pastures, and before improved rotations were introduced after draining and deep ploughing, was perhaps the most profitable course. The cultivation of heavy wet lands is so much more precarious than that of arable that a little improvement has been greatly attended on the improvement as the light turnips soils. Of late these lands have been found susceptible of a great improvement, by thorough draining; the crops are found not only more abundant, but also more certain; and the inconvenience of not being able to plough and work these soils in spring is obviated by the perfect draining. When this system is more generally adopted on heavy soils, it will be found that the present disinclination of farmers to take farms on such soils will cease, and give place to the more salutary predilection for heavy lands, which will bear wheat and beans with little exhaustion.

The cultivation of flax and hemp, which was very common formerly, has now been long discontinued, owing to the competition of the foreign growers: but if ever the present protection given to the growers of corn be removed by an alteration in the corn laws, the comparatively unprotected produce, such as flax and hemp and linseed, will no doubt draw the attention of the farmers again.

Grass-land being abundant and the climate favourable to pastures, a great deal of the land is kept in grass and the maintenance of cattle. Good meadows let at a high rent, and are carefully manured with composts. Great crops of hay are made in favourable years, and, as those who keep many horses, and generally live by the hay of, it is seldom sold in the dry state. Young cattle are kept on the inferior lands in summer, and have hay and straw in winter, with turnips where these are raised: a few are fattet at three years old, but most of them are sold as graziers in Yorkshire and Lancashire. Scotch cattle are the value in September, at the great fair at Brough-hill, held in that month: they are wintered in coarse pastures and occasionally in straw-yards; the next year they are put on the best grass and are fit for the butcher in October. A few horses are kept in the same mode, but not to any considerable number, and are fit for the mountain-pastures; they are brought down to the valleys at the approach of winter and kept in the enclosed grounds till April. The folding of sheep on turnips is not so general as it ought to be, especially on the gravely and sandy soils of the county. There are many fairs, which are to be judged of by the extent of land on which turnips are raised to be eaten on the land by sheep. The plantations are extensive in most parts of the county.

The bishop of Carlisle has already been mentioned, made considerable plantations of oak, ash, elm, beech, sycamore, Scotch fir, and larch, which last have thriven best. Many ornamented cottages and small villas have been built on the borders of the several lakes; and men of talent and reputation have taken up their residence in the district, and increased the value and beauty of the county. There has tended to improve the immediate neighbourhood more rapidly than would otherwise have been the case. Yet this improvement seldom extends far from the centre where it commenced; and many districts, which were cultivated by their own inhabitants, remain uncultivated, and present to the view of the traveller cultivated fields. If something should be lost in picturesque scenery, much might be gained in usefulness; and the intermixture of uncultivated farms and barren rocks would not render the scene less interesting.

The fattening of hogs and the curing of bacon and hams are well understood in Westmoreland, and many hams are sent to other parts of the country. The breed is not large. The hogs are not made to follow the plows in some places, the hams are more delicate, and are very well cured and smoked. They are often sold as York hams, whereas the latter are much larger and fatter, the Yorkshire breed of hogs being large and fattening very readily. Although the curing of hams is tolerably well understood in most places, it may be greatly raised by a judicious outlay of capital, either by planting or by cultivation. Draining can be effected at a small expense, where stone is so abundant: lime is cheap, and labour reasonable: with these provisions the country is in a good position to present to the view of the traveller cultivated fields. If something should be lost in picturesque scenery, much might be gained in usefulness; and the intermixture of uncultivated farms and barren rocks would not render the scene less interesting.
The parish of Kendal, which extends into Lonsdale ward, has an area of 68,360 acres, and is divided into twenty-seven townships of parishes, each separate, maintaining its own poor; the population of the whole parish in 1817 was 17,564. The parliamentary borough comprehends the two townships of Kirkby Kendal and Kirkland, and such parts of the township of Nether Graveshop as are adjacent to the township of Kendal. The statistics of the three townships in 1817 were as follows:

- **Kirkby Kendal:**
  - Area: 2,110 acres
  - Population: 5,328
- **Kirkland:**
  - Area: 2,200 acres
  - Population: 1,160
- **Nether Graveshop:**
  - Area: 1,850 acres
  - Population: 312

This statement does not exactly give the statistics of the parliamentary borough, since it includes a portion of the township of Nether Graveshop which is not comprehended in the borough, and which indeed, naturally, has no municipal distinguishing. The difference however is not of great importance.

The town is chiefly on the slope of a hill rising from the right or western bank of the river Kent; one principal street runs to the northward from the church; two others are divided at the town end in five divisions, and are divided into four wards, which, with their areas, relative position, and population in 1831, are as follows:

<table>
<thead>
<tr>
<th>Name of Ward</th>
<th>Position</th>
<th>Area in Acres</th>
<th>Population in 1831</th>

</tr>
</tbody>
</table>

The town of Kendal is included in Kendal ward; the other wards are in the market-town of Kendal, and the market-town of Kendal, Kirkby Kendal, Kirkby Stephen, Milnthorpe, Onod, and Shap. Appleby is described elsewhere. [APPLEY.]

Kendal, more accurately Kirkby Kendal, or Kirkby in Kendal, the town, and the church is on the site of the old or the new, and is in Kendal ward, 263 miles from the General Post-Office, London, viz. 241 miles by railway to Lancaster, and thence by coach 22 miles. It was made a market-town by licence from Richard I., and became, by the settlement of the Farnings, in the reign of Edward III., the seat of a considerable manufacture of woollen cloths (which took from the town the name of Kendale), and continued to be so down to quite modern times: indeed the woolen manufacture is not quite extinct even now. The town was incorporated in 1678 by Queen Elizabeth. Before the turnpike-road was made in 1752, nearly two hundred pack-horses were employed weekly, some of them making two journeys in the week, in bringing provisions and divers articles from the town, or manufactories; besides two waggons twice a week from Lancaster, carrying in all about sixty horse-loads, and two or three carts making several journeys, and carrying altogether about forty horse-loads weekly between Kendal and Millthorpe. The parish of Kendal, which extends into Lonsdale ward, has an area of 68,360 acres, and is divided into twenty-seven townships of parishes, each separate, maintaining its own poor; the population of the whole parish in 1817 was 17,564. The parliamentary borough comprehends the two townships of Kirkby Kendal and Kirkland, and such parts of the township of Nether Graveshop as are adjacent to the township of Kendal. The statistics of the three townships in 1817 were as follows:

The living of Kendal is a vicarage of the clear yearly value of 300l., with a glebe-house; the vicar presents to the perpetual curacy of St. George, which is of the clear yearly value of 200l. Thirteen of the townships in the outport of the parish constitute distinct chapels, and there is another chapel (Burneside) in the parish: with two exception, the following gives the number of persons authorized to serve the several curacies in these chapels. The parish is in the rural deanery of Kendal, in the archdeaconry of Richmond, in the diocese of Chester.

There were, in 1833, in the three townships composing the borough, an infant-school with 90 children; three dame-schools, or other schools for children quite young, with 66 children of both sexes; thirty-five other day-schools, with 1212 scholars, namely, 286 boys, 330 girls, and 557 children of sex not distinguished in the return; giving a total of 151 children, or between one in eight and one in nine of the population, under daily instruction. There were besides 12 persons under instruction in the evening. One of the day-schools, with 12 boys, was a free grammar-school; two others, with 67 boys, were ragged Schools. Cauden notices that there were five in the county; and another by endowment subscription; and two others, with 145 boys and 172 girls, were national schools, partly supported by endowment and subscription, and were Sunday-schools also. There were, besides these, nine Sunday-schools, with 738 children; making a total of 1114 children, or less than one in ten of the population, under instruction on Sundays.

In the outskirts of the town were twenty-four day-schools of all kinds, with from 725 to 735 children, namely, 277 boys and 458 girls; and 203 boys and 238 girls, in the returns; with 151 boys and 151 girls, in the returns; giving nearly one in eight of the population, under daily instruction; there were also eight Sunday-schools, with 442 scholars, namely, 224 boys, 173 girls, and 45 of sex not distinguished in the returns; giving about one in thirteen or fourteen under instruction on Sunday.

The Easter, Michaelmas, and (by adjournment) the Epiphany sessions for the county are held at Kendal, and the town is one of the polling-stations for the county. It is the seat of the Kirkby family, which is partly in Windermere, but chiefly in Grassmere parish, both in Kendal ward, 14 miles north-west of Kendal, and 277 from the General Post-Office, London, by railway to Lancaster and thence by coach through Kendal. Cauden notices that there were five in the county; and another by endowment subscription; and two others, with 145 boys and 172 girls, were national schools, partly supported by endowment and subscription, and were Sunday-schools also. There were, besides these, nine Sunday-schools, with 738 children; making a total of 1114 children, or less than one in ten of the population, under instruction on Sundays.

The living of Kendal is a vicarage of the clear yearly value of 300l., with a glebe-house; the vicar presents to the perpetual curacy of St. George, which is of the clear yearly value of 200l. Thirteen of the townships in the outport of the parish constitute distinct chapels, and there is another chapel (Burneside) in the parish: with two exception, the following gives the number of persons authorized to serve the several curacies in these chapels. The parish is in the rural deanery of Kendal, in the archdeaconry of Richmond, in the diocese of Chester.

Brough, or Burgh-under-Stainmoor, is in the East ward, 252 miles from the General Post-Office, London, by ex-mail road to Carlisle and Glasgow, or 28 miles north-east of Kendal, and 291 from London by railway to Lancaster and thence through Kendal. Many Roman coins have been dug up, and some antiquaries have identified the place with the Roman station Verternum by Minus. The town had antiently a castle, which was, together with the town, taken and sacked by King William of Scotland in A.D. 1174. The castle was ruined by an accidental fire A.D. 1521, but was repaired by Anne, countess dowager of Brough and Holme, in 1600. Its remains stand on an eminence, in the midst of what is supposed to have been the Roman station. The chief part still standing are some portions of the keep and some other towers: the keep is, in its general form and appearance, similar to those of Richmond Castle, &c. The whole parish has an area of 22,650 acres, and had, in 1831, a population of 1882, besides those contained in Kaber township, which was partly in Kirkby Stephen. The town is in the right hand return, had, in 1831, 191 houses, namely, 181 inhabited, 8 uninhabited, and 2 building, with a population of 212 families, or 966 persons. The town is divided by the Mersey, a small stream, into a north and south portion, and the two villages are respectively designated Market Brough and Church Brough, the former on the north, the latter on the south side of the stream: the houses are plain, but tolerably commodious. The church is large, but of poor architecture, and stands on the remains of a charred emblazoned wall, and in the windows is some ancient stained glass. There are meeting-houses for Methodists and Independents. The market is on Thursday, but is of little importance. There are two great cattle-markets yearly, and a weekly fair on Saturday. The Brough-hill Fair, is held on a common two miles from the town, near the Appleby road, and is a great fair for cattle, horses, wearing apparel, and hardware. There are small-paths and small-stalls; the market is composed of 63 men in 1831. The living is a vicarage, of the clear yearly value of 492l., with a glebe-house, in the rural deanery of Westmoreland, in the archdeaconry and diocese of Carlisle. There is a chapel at Stainmoor in the parish, the perpetual curacy of which is of the clear yearly value of 113l. There were in the whole parish, in 1833, nine day-schools of all kinds, with 302 scholars, namely, 115 boys, 62 girls, and 125 children of sex not stated in the return; giving nearly one in six of the population. On Stainmoor there was also a Sunday-school, and there were four other Sunday-schools: the whole contained 193 scholars, namely, 25 boys, 30 girls, and 138 children of sex not stated; giving rather more than one in ten of the population under instruction on Sunday.

Burton in Kendal is in Lonsdale ward, in the southern part of the county, near the border of Lancashire, 202 miles from the General Post-Office, London, chiefly by railway, on the road from Lancaster to Kendal, about 11 miles from each of those towns. The parish has an area of 9170 acres, and extends into Kendal ward, and into the hundred of South Lonsdale in Lancashire: the population, in 1831, was 1831. The township of Burton in Kendal, in which the town stands, had, in 1831, 107 houses, namely, 152 inhabited, 14 uninhabited, and 1 building, with a population of 136 families, or 733 persons. The town is well built, and has a respectable appearance, although many of the houses are old; there is a good market-place, with a stone archway in the centre of the church; and the church is in a good state of repair, with a square tower: there is a meeting-house for Independents. There are some manufactures of linen and canvas in the parish, which employed, in 1831, 44 men in the township of Holme. There were, in the parish, in 1831, 125 children of sex not stated in the return; giving nearly one in five of the population. The living is a vicarage, of the clear yearly value of 191l., with a glebe-house, in the rural deanery of Burton, in the archdeaconry of Richmond, in the diocese of Chester. The perpetual curacy of the chapel of Pres-
The inhabitants of the parish are divided into two main groups: 1. The village itself, consisting of a large number of cottages and small houses, most of which are inhabited by farmers and their families. 2. The surrounding countryside, which is dominated by agriculture and forestry.

The village is situated on a hill overlooking the River Lune, which flows to the south. The parish includes a large area of arable land, with a smaller proportion of woodland. There are several small streams and rivers, including the Millthorpe Burn and the Kirkby Burn, which provide water for irrigation and fishing.

The church, St. Michael's, is a large and imposing building, with a tall spire and a number of stained glass windows. It is a fine example of the Perpendicular style of architecture, with detailed carvings and sculptural work. The churchyard contains the graves of many notable figures from the community, including local landlords and landowners.

There are several schools in the parish, including a grammar school and a number of primary schools. The parish has a good standard of education, with high levels of literacy and numeracy. The schools are well-equipped with modern facilities, including computers and interactive whiteboards.

The church is also active in the community, with a strong tradition of voluntary work and charitable giving. There are numerous clubs and societies, including a local history society, a gardening club, and a women's institute.

In conclusion, Kirkby Lonsdale is a peaceful and serene village, with a rich history and a vibrant community. It is a place where people can live and thrive, with access to good education, healthcare, and amenities. The parish is well-served by its infrastructure, with well-maintained roads and pathways, and a good public transport network.
West

Lancaster; and 18 miles north by west of Kendal. There was antiently in this parish a Premonstratensian abbey, founded originally at Preston in Kendal (now Preston Patrick, a township in the parish of Burton in Kendal) by Thomas, son of Gospatrick or Cospatrick, not in the reign of Henry I., as stated by Nicholson and Burn, but in the reign of Henry II. This abbey was situated near the small river Duddel. The present abbey is that which was formerly the abbot's house, and is situated on the banks of the river Eden. The present abbey was, in all probability, built by the canons of the abbey. The church was not a collegiate church; it was a priory, and the абобы were only the lessees of the property of the abbey. The present abbey is a small, one-story building, with a gabled roof, and contains only one room, the chapel of the abbey. The abbey was an important centre of learning and culture in the region, and was attended by scholars from all over Europe. The abbey was dissolved in 1540, and its property was given to the Crown. The abbey was later sold to the Duke of Lancaster, and in 1571 it was granted to the see of York. The abbey is now a ruin, but its foundations can still be seen. The parish, including part of the chapelry of Mardale, has an area of 27,770 acres. There were, in 1836, 198 houses, namely, 190 inhabited and 8 uninhabited, with 948 persons, of these, 8 houses (6 inhabited and 2 uninhabited), 6 families, and 23 persons were in the chapelry of Mardale; but we have no means of ascertaining what proportion of the remainder belonged to the town and its immediate neighbour-hood; two-thirds of the population of the town, as is commonly the case, are agricultural. The town consists of one long street, extending along the mail-road from Lancaster to Kendal to Carlisle and Glasgow. The church is on the east side of the town, and retains some ancient parts amid many alterations. There is a prison at the town; and the prison of Lancaster, which is small, is held on Monday; and there is one yearly fair for cattle and pedlery; there are some limestone and slate quarries. The living is a vicarage, and consists of the whole value of 7½, with a glebe-house, and vicarates in the presents to the rectories of Blundells and Kirkby Lonsdale. There are in the parish, in 1833, three day-schools, with 62 scholars, namely, 13 boys, 7 girls, and 38 children of sex not stated in the returns; giving only 1 in 18 of the population under daily instruction. There were no Sunday-schools.

Divisions for Ecclesiastical, Legal, and Parliamentary Purposes.—The county is divided between the dioceses of Carlisle and Chester; the Eastern and Western, constituting the ancient barony of Westmoreland, form the rural deanery of Westmoreland, in the archdeaconry and diocese of Carlisle: Kendal and Lonsdale wards are included in the rural deanery of Kendal, in that part of the archdeaconry of Kendal, with the exception of Kirkby Lonsdale parish and its dependent chapels, which are included in the rural deanery of Kirkby Lonsdale, in the same archdeaconry and diocese. Both the rural deaneries of Kendal and Kirkby Lonsdale consist of several parishes in the county of Lancashire. The number of parishes in the county is comparatively small, being only thirty-two; but as many of the parishes, from their great extent, which averages more than 15,000 acres, or nearly 24 square miles each, and rises in some instances (Kirkby Stephen and Kirkby Lonsdale) to above 30,000 acres, and in one instance (Kendal) near to 70,000 acres, have been divided into chapels, the number of ecclesiastical charges is much greater, as the following table shows:

<table>

The dioceses of Carlisle and Chester are both in the ecclesiastical province of York, in which consequently the whole county is included.

P. C., No. 1712.

The county is included in the northern circuit. The assizes are held at Appleby. The latter half of the last century; and many alterations have been made since that time. The county is not a market or county town, but it is a busy and thriving place. The county is divided into the following parishes:

<table>

</tr>
</tbody>
</table>

There is a manor house at Kendal, and a mansion house at Kirkby Lonsdale. There are three market towns in the county: Kendal, Kirkby Lonsdale, and Kirkby Stephen. The county is divided into two archdeaconries, that of Carlisle and that of Chester. The latter half of the last century; and many alterations have been made since that time. The county is not a market or county town, but it is a busy and thriving place.

History and Antiquities.—In the earliest historical period this county appears to have been included in the extensive territory of the Brigantes (Brii-gan-tes). Ptolemy, and upon the subjugation of South Britain by the Romans, it was comprehended in the province of Maxima Caesariensis. There is no evidence that this county was ever occupied by the Romans, and the only vestiges of Roman occupation are the remains of a bridge at Kirkby Lonsdale, and a milestone at Kirkby Stephen. The county was inhabited by the Brigantes, and their name is still borne by the inhabitants of the county. The Brigantes were a warlike nation, and were proverbial for their bravery. Their language was the Brigantian, which is still spoken by the inhabitants of the county.

A Roman road ran through the county nearly in the line of the main road from Liverpool to Carlisle, and is still traceable in many parts of the county. The county is divided into two archdeaconries, that of Carlisle and that of Chester. The latter half of the last century; and many alterations have been made since that time. The county is not a market or county town, but it is a busy and thriving place.
the county on the east side, and crossing Stainmoor, ran north-westward by Brough, Warcop, Bongate, and Clappergate, suburbs of Appleby, Kirkby Thore, and Temple
Bowerby, to Brougham, where it crossed the Embom into Yorkshire, as is clearly seen from Kirkby Thore and Vesey (a
few years since) tolerably perfect: it is there six yards wide, and, on level ground, is formed of three layers of
stone, of the aggregate thickness of a yard, the lowest layer being the largest. In other places it was sometimes made of
sand. A road and bridge branched off from this at Kirkby Thore and ran northward over the moors to Caervorran, one of the stations on the Roman Wall, in Northumberland. An antient camp, or
fort, an oblong quadrangle of irregular form, stands on the east side of the Roman Way (or a small round camp) east of Stainmoor, and so exactly on the border of Yorkshire and Westmorland, that part of the camp is in
each county. The fragment of Re-Cross or Here-Cross, the antient boundary-mark of the Scottish principality of Cumber
land, and now of Westmorland and Yorkshire, stands inside the camp. A square stone fort called Maiden Castle,
defended by two ramparts, an inner one of stone with a small ditch, and an outer one of earth with a ditch, stands on
the east end of the road, about two miles west of the camp just noticed.

The Antonine station or town Verteor is by Horsey and other antiquaries fixed at Brough. Mr. Reynolds, in his
'tier Brituanaariam,' fixes Verteor at Bowes in Yorkshire (where a Roman road branches off to another station as has
been the Lavarem of Antoninus), and considers Brough as having been the Brovovacum of Antoninus. Brovovacum is
by Horsey and others fixed at Kirby Thore, to the southeast of which village, on Speedy Moor, are the remains of a
castrum, named Procopiae, of which Thorpe, the principal place standing on the banks of the Wen, where the
Maiden Way diverged from the principal Roman
road. In the neighbourhood of this camp or fort, if not on the site of it, the remains of buildings, consisting of
walls and arched chambers or vaults; a Roman altar, with the inscription of a man named Claudius; and several stones,
and other antiquities, have been dug up. A Roman inscription, 'Deo Belaestvarudo lib. votvm fecit Iovis,' was
dug up here.

The town of Amboglanmv is fixed by Horsey and of Brough. Mr. Reynolds thinks Brocavum to be the same as
Brovovacum which he fixes at Brough; but a comparison of the second tier of Antoninus with the fifth, leads us to coincide in the opinion that they are different places. Some antiquaries have proposed to fix the
Ambalab of the Notitia at Appleby, missed apparently by the similarity of the names; and perhaps for a similar reason Ambogogana has been identified with Ambleside: but by Horsey and most other antiquaries, Ambogogana and Amboglanum have respectively been fixed at Horsley (or Ducket Cross), on the line of the Wall. Horsley proposed to fix the Calatum (Kalavos of Ptolemy, one of the towns of the
Brigantes, which is apparently the same as the Galeum of Antoninus) at Appleby; Camden had identified it with the
site of Brough, an embankment with a ditch inside, which some suppose to fix it at Kendal. The Alone of Antoninus, or, in the Notitia, Aliunc, which Horsley fixes at Whitley Castle in the
south-west corner of Northumberland, others propose to fix at Ambleide, where the evident traces of a
Roman station or town have been observed; and there, which a Roman road ran from Kendal in the direction of
Keswick. Horsley would fix the Dictis of the Notitia at Ambleside.

A number of Roman inscriptions have been found in Westmorland, several of which are given in Horsley's 'Britannia Romana:' none of them however assist us in
fixing the position of the several towns mentioned above.

There are a number of camps and earthworks in Western England (or a related period) of which it is doubtful
whether any of them are to be referred. Near the south end of Dun Fell, on Millburn Forest, is a round camp or fort, surrounded with deep ditches, called 'Green Castle.' An altar, with the inscription Deo Silvanus, was found here. There are several remains of camps and roads on the waste ground of Millburn Forest. At the end of Wanshaw-wood, on the west bank of the Lowther, opposite Lothter Hall, is another round fort called 'Castlesteads;' and at the
south end of Emont bridge is a circular enclosure, formed by a small ditch, and the banks of the river which have
probably been supposed to be a lating-ground of the middle ages.

It is called 'Arthur's round table.' At Tebay near Oxton, on the banks of the Lune, is a circular mound with a trench
round it, partly washed away by the stream. At Sayle Bottom near Great Asby are a number of barrows, with a
large fort and a trench, and a knoll of the same size, on the other side of the river, which they occupy; and at Sandford, between Warcop and Appleby, near the line of the Roman road, are some
more barrows, two small camps, and the ruins of a small round fort, the walls of which are of immense thickness and built
with red stone. The Maiden Castle, near the middle of the

There are some monuments generally regarded as Druidical.

Near 'Arthur's Round Table' was found in 1800, under an artificial hillock, a complete circle of stones en
closing an area nine feet in diameter, and having in it a
large round stone. There is a similar enclosure of two or three yards in diameter, called 'the Druids' Cross.' Another circle
twenty-one yards in diameter, called 'the Cock-stones,' stands at the head of Ellerbeck, in the neighbourhood of
Ulleswater; and there is a large cairn on the descent from the hill. There is a circle seventy feet in diameter, formed of large
stones, on Lowther Scar; and near Shap is the remains of
two converging lines of huge stones of unbewn granite,
called 'Curl Lofts.' Pennant, who has described the
bottom, near Shap, is a circle of stones called 'the Druids' Temple,' which has certainly been used for a burying-place.

Westmorland was probably conquered by the Angles of Northumbria, under Egfrid, who took several towns near
the side and Carleile from the Cumbrian Britons, about A.D. 665. It became part of the
kingdom of Northumbria, of which it shared the fate. The county is mentioned only once in the Saxon Chronicle,
where it is called Wessex. It is merely recorded to have been ravaged (A.D. 966) in the reign of Edgar by Thored the son of Gunner, probably a Danish chieflain. In the later Anglo-Saxon and in the earlier Anglo-Norman period it is said to have been included in the kingdom of
the Scots, and during the reigns of David and William the Conqueror erected the
baronies of Westmorland and Kendal. Little notice of the county occurs in history, except in the record of some of the Scottish invasions. Appleby Castle was taken by
the son of Aymer de Lancastre, and the town destroyed; and the town was again destroyed by the Scots in the reign of
Richard II. The barony of Kendal was held by the family of
Talilebois or Talebois, who after a time took the name of
Le Lanceastre, and Fitz-Reinidef, the members of which
family also took the name of De Lancastre. The chief
motive of the family failing, the inheritance was divided: one
part, called the 'Richmond Fee,' came to the Lindsey
family; another part, the 'Marquis Fee,' to the Rosa family, afterwards by marriage to the Purr and; and the third
called the 'Baron Fee,' to the family of Lumley. The barony of Westmorland was at first united with that of Cumberland, and held by the family of
Le Meschieris, and then by other families. Until, by
favour of Hugh of Lacy, that period for which was created
by Richard II. in favour of Ralph Nevill of Raby, whose heirs
held the earldom until it was forfeited by Charles Nevill, who was one of the leaders of the great rising in the north
against Queen Elizabeth.

The county is divided into four: Appleby [APPLEBY], Kendal, Brough, Buley, Howgill, and Brougham, with Shap Abbey, are the
principal remains of the buildings of the middle ages. Kendal and Brough Castle and Shap Abbey have been noticed. Bailey or Bawley Castle is on the left bank of the Eden below Appleby, and is a mere ruin, showing little remains of its former strength. Howgill Castle, near Milburn on the northern border of the county, is occupied as a farm-house; some of the walls are more than ten feet thick. Of Brougham Castle there are considerable remains. The keep is standing, but all the inner apartments are destroyed, except one vault, the roof of which is formed of groined arches supported by an octagon pillar in the centre. Castle Fields, on Orton; is a walled enclosure, now in ruins, apparently in place of security for cattle during the inroads of the Scots.

In the civil war of Charles I., Appleby Castle was occupied by a royalist garrison, but was obliged at last to surrender. Much is still evident on the islands in Windermere was the stronghold of Colonel and Major Phillipon, brothers, royalists. The major by his daring exploits acquired among the Parliamentarians the nickname of Robin the Devil. In the rebellion of 1745-6 there was some little fighting at Kendal (14th December, 1745), between the townspeople and a party of the rebels then on their retreat toward Scotland; and a few days after a rather severe skirmish at Clifton, on the road to Penrith, between the rear-guard of the insurgents and the garrison of Appleby Castle is on the left bank of the Eden below Appleby, and is a mere ruin, showing little remains of its former strength. 1839 was 69, or 1 in 19; in England, 1 in 20. The number affiliated in 1834-5 was 69, and 65 in 1835-6. The proportion per cent. of persons married under 21 years of age in the three years ending 30th June, 1841, was 9:57 for women, and 2:82 for men; in England and Wales 13:79 for women, and 4:09 for men: in England and Wales, 9:6 for the two sexes.

The annual value of real property assessed to the property tax in 1815 was 258,199.; property assessed to occupiers, 263,893.; and the profits of trades, professions, &c. were assessed at 61,892. In 1825-6 the centesimal proportion of the various descriptions of property assessed was:—land, 67:6 per cent.; dwellings, houses, and other buildings, 52:4 per cent.; mills, factories, &c., 18:6 per cent.; personal property, &c., 4:0 per cent. The net rental or annual value of real property assessed to the poor-rate in 1841 was as follows:—

<table>
<thead>
<tr>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>In land property</td>
<td>£221,054</td>
</tr>
<tr>
<td>Dwellings-houses</td>

</tr>
<tr>
<td>All other kinds of property</td>
<td>7,907</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>£266,335</strong></td>
</tr>
</tbody>
</table>

In the above year the total amount levied for poor-rates was £22,829, being a rate of 1s. 8d. in the pound on the annual value of real property assessed. Taking the annual value of real property in the county in 1841, the rate per head was 4:14. 4d. for each inhabitant; and dividing it by the number of acres, it was 9s. 1d. per acre, which is lower than for any other county in England, and 2d. under the average for Wales.

The county-rate levied at different periods, and the principal disbursements, are shown in the following table:

<table>

</tbody>
</table>

The particulars of the county expenditure in 1834 are as follows:

- Bridges, building, repairs, &c. £257
- Gaols, houses of correction, and maintaining prisoners 1065
- Shire-halls and courts of justice 6
- Prisons 250
- Clerk of the peace 110
- Conveyance of prisoners before trial 27
- Conveyance of transports 25
- Vagrants, apprehending and conveying 9
- Constables, high and special 106
- Coroner 47
- Miscellaneous 302

**Total Income**: £3647

The number of turnpike trusts in 1840, was 10; the income from tolls was £834.; parochial compositions in lieu of taxation, £184.; and total income, £914.; the total expenditure for the same year being £869. The bond and mortgage debts amounted to £62,406. In 1836 the debt was equal to 8:4 years' interest; for the whole of England the proportion of income to debt being 4:5 years' income: the proportion of unpaid interest to the total debt was 3 per cent. for Westmoreland; for England it is 12 per cent.

In 1839 the church-rates in Westmoreland amounted to £2651, and the amount from estates and rent charges applicable to the same objects was £271. in 1832. The sum of 10334. was expended in 1839 for the purposes of the establishment, of which 5554. was for repairs of churches.

**Crime**—Number of persons charged with criminal offences in the septennial periods ending 1819, 1826, 1833, and 1840.

The numbers committed, convicted, and acquitted in each year from 1834 to 1842, were as under:

- 1834: 23, 3517, 3036, 4683, 138, 25, 26, 6
- 1835: 24, 3517, 3036, 4683, 138, 25, 26, 6
- 1836: 25, 3517, 3036, 4683, 138, 25, 26, 6
- 1837: 26, 3517, 3036, 4683, 138, 25, 26, 6
- 1838: 27, 3517, 3036, 4683, 138, 25, 26, 6
- 1839: 28, 3517, 3036, 4683, 138, 25, 26, 6
- 1840: 29, 3517, 3036, 4683, 138, 25, 26, 6

Of 201 persons committed in the nine years from 1834 to 1842 inclusive, 19 were for offences against the person; 27 for offences against property committed with violence; 225 for offences against property committed without violence; 25 for malicious offences against property; 3 for forgery and other offences against the currency; and 5 for offences not included in the preceding classes. The number of females committed was 53. Taking the mean number of committals for 1840-41-42, the proportion of persons committed in one year to the population was almost in 1500, while for England and Wales it is about 1 in 500.

Of 39 offenders (30 males and 9 females) tried at the assizes and sessions in 1842, there were two charged with offences against the person; 7 with offences against property committed with violence; 25 (including 19 cases of simple larceny) with offences against property committed without violence; with malicious offences against property, none; for uttering base coin, none; and 1 for misdemeanour. In no one case was sentence of death recorded. Of 31 persons convicted, 1 was transported for life; 5 for periods above ten and under fifteen years; for periods above seven and under ten years, none; and 5 for terms of seven years, making 9 transported. None were sentenced to imprisonment for a period exceeding one year; 5 were imprisoned for above six months and less than one year; and 17 for six months and under. Of the 8 persons acquitted, 5 were found not guilty on trial; in the case of 2 no bill was found; and in 1 instance there was no prosecution at all. The degree of instruction was ascertained in all but one case: 4 males and 1 female could neither read nor write; 22 males and 8 females could read and write imperfectly; 1 male could read and write; and 2 males and 1 female had received some prior education.

**Saving Banks**—There is only one of these institutions in the county, in Kendal; and the number of depositors and amount of deposits in each of the following years were as under:

- 1833: 712
- 1834: 824
- 1835: 977
- 1836: 999

**Am. of deposits**: £422,813, £429,270, £436,553, £435,471, £434,292, £433,826

The distribution of the sums invested in 1830, 1834, and 1839 is shown in the following table:

| Year | Depo. Depos. Depos. |
|------|---------------------|---------------------|
| 1830 |                      |                     |
|      | Depos. Depos.       |                     |
|      |                      |                     |
| 1834 |                      |                     |
| 1839 |                      |                     |

The deposits of 8 friendly societies, not reckoned above, amounted, in 1840, to 1202.

**Electric Franchise**—The number of county voters registered, in 1835-6 and 1839-40, was as under:

- 1835-6: 1835-4
- 1839-40: 1839-40

**Freeholders of every class**: 3,294
**Copyholders and customary tenants**: 275
**Leasesholders for life or term of years**: 130
**50. tenants at will**: 1,005
**Trustees and mortgages**: 3
**Qualified by office**: 15
**Joint and duplicate qualifications**: 119

- 1835-6: 4,815
- 1839-40: 4,490
Ea»t-?ca^a. better to 3^25 10 was. an. the part and. 2,2i7 the I.9S2 »> L558.10. 143 provinces 705 west the this 1802, when, the archbishopric was abolished, and the duchy was assigned to Heise-Darmstadt, which ceded it to Prussia in 1811. It had at that time an area of 1500 square miles with 131,715 inhabitants. This duchy of Westphalia, which was bounded on the east by the circle of the Upper Rhine, and on the three other sides by that of Westphalia, did not form a part of that circle, but belonged to the latter.

WESTPHALIA, the circle of, was, till the peace of Luneville, one of the largest circles of the empire, its area being about 27,000 square miles, with 2,560,000 inhabitants. It was bounded on the west by the Netherlands, on the north by the German Ocean, on the west by Lower Saxony, and on the south by the circle of the Lower Rhine, and comprehended the bishoprics of Münster, Paderborn, Osnaburg, Liege, and Corvey, the duchies of Jülich, Cleves, and Oldenburg, the principalities of Minden, Verden, and Friesland, the counties of Ravensburg, Mark, Hoya, Diepholz, Schaumburg, Lippe, Bentinck, Tecklenburg, Lingen, Steinfurt, Rietberg, and many ecclesiastical and temporal lordships.

The peace of Tilsit made Napoleon master of all the Prussian dominions as far as the Elbe, and he occupied the electorates of Hesse and Hanover, and the duchy of Brunswick. He did not think it necessary to extend the boundaries of the French empire beyond the Rhine, but he resolved to form a part of these countries into a state dependent on France.

WESTPHALIA, the kingdom of, was created on the 1st of November, 1807, and comprised the territories of Brunswick-Wolfenbüttel and Hesse-Cassel (with the exception of Hanau and Kassel), the Prussian provinces of Magdeburg and the Old Mark on the left bank of the Elbe, Hanover, Hildesheim with Goslar, Mansfeld, Querfurt, Halberstadt, in the state of the electoral Palatins, and the electoral Palatine circles of Schleusingen and Lauenburg.

The area of this new kingdom was 14,560 square miles, with 1,947,000 inhabitants. Napoleon made his youngest brother Jerome, king, who arrived on the 7th of December, in the capital city, Cassel, bringing with him a constitution, which, though it was framed entirely on the French model, and overthrew all the old forms, might have promoted the welfare and happiness of the people had it been strictly adhered to.

The new kingdom was by no means prosperous in the territories which had previously been possessed by the Electorate of Hesse, and were now drained by the French, and some were completely exhausted; in addition to this, Napoleon reserved the half of all the domains to reward his marshals, generals, and others, a garrison of 60,000 men to be kept in Magdeburg, and not only supplied with provisions and clothes, but the large arrears of the military contributions which had been imposed on the several provinces were to be paid to France. Yet in spite of all this, the country gradually revived; an army of 16,000 men was soon formed; the introduction of the French codes, and the many innovations introduced with the new government, were not indeed calculated to please the people, yet they became accustomed to them, and found themselves in a better situation. Some of the dependent counties, and the government acquired strength and security.

But the war between France and Austria in 1809, caused some internal troubles, which gave occasion for many severe measures. The king was compelled to increase his army to 30,000 men, which gave occasion to increase the tax of customs and excise, in order to raise the necessary funds. In 1812, the army was increased to 32,000 square miles, with 2,500,000 inhabitants, of whom 1,947,000 were of the new kingdom; a great number of them were of the soldier class, and many of the people, who had been dependent before the war, found themselves in a better situation. But the war was most agreeable to the people, who were not only supplied with provisions and clothes, but the large arrears of the military contributions which had been imposed on the several provinces were to be paid to France. Yet in spite of all this, the country gradually revived; an army of 16,000 men was soon formed; the introduction of the French codes, and the many innovations introduced with the new government, were not indeed calculated to please the people, yet they became accustomed to them, and found themselves in a better situation. WESTPHALIA, THE PRUSSIAN PROVINCE, was constituted in 1815, of the duchy of Westphalia and of several principalities, some of them former possessions of Prussia, and the remainder obtained partly by cession or exchange, and partly by the decision of the Congress of Vienna. It is situated between 50° 43' and 52° 30' N. lat. and 6° 25' and 9° 20' E. long. Its area is 7,900 square miles, with 1,385,000 inhabitants. It is bounded on the north-west by Holland; on the north-east by Denmark; on the west by the province of Hesse-Cassel, and on the south-west and west by the province of Jülich-Cleve-Berg.

The principal rivers are the Weser, the Ems, the Lippe, the Rühr, and the Vechta. There are no lakes in this province, nor any large ponds or meers: there are numerous marshes, especially in the northern part; the principal rivers are those of the Rhine and the Ruhr. The climate is temperate and healthy: the air is pure, but colder in the southern than in the northern part, where fogs caused by the marshes, are frequent. The winter is cold, the snowset, and the heat in summer is often insupportable in the flat lands. The order of the Rhine is more common in the plain than in the moun-"}

The cabinet is campanulate, 5-lobed, and yellow. The corolla has a short tube, naked inside; the throat is wide, blotched lilac; the upper lip is flat, bifid, rather spreading; the lower lip spreading, 3-lobed, the middle lobe rather bifid. The stamens 4, erect, distant, included in the tube of the 1-celled glabrous anthers; the two sterile, with bilaterally attached, dependent and empty; and linear lobes. The style is equally bifid at the top; the lobes are subulate, with a stigmatic surface at the apex. The scheme of corolla consists of 4 in the ordinary number. An account of the species of this genus described. They are pretty shrubs, and might be cultivated with advantage for va-"}

WETHERBY. [YORKSHIRE.]

WETSTEIN, JOHN JAMES, distinguished for his labours on the Greek New Testament, was descended from a family which long held an important station in the city of Basel. His grandfather, John Rudolph Wetstein, who was born in 1564 and died in 1624, was professor of Greek, and afterwards of divinity, in the univer-"}

The subject of the present notice was born at Basel in 1693. After having studied divinity under his uncle the professor, and Hebrew under Buxtorf, he was admitted a minister of the national church in 1718, on which occasion he defended his Latin thesis on the genuineness and authenticity of the commonly received text of the Greek Scriptures, under the title of "Dissertatio de Variis Novi Testamenti Lectionibus," 4to. To this subject he may be said to have been henceforth devoted his life. He commenced by visiting France and England, as well as the various libraries in Holland, for the examination of manu-"}

It was not till 1730 that Wetstein produced his next publica-"}
the Remonstrants or Armenians appointed him successor to Le Clerc in the professorship of philosophy and history, and although, on his making a public apology for some opinions favourable to Socinianism which had been ascribed to him, the decree of the Basel senate was reversed in May, 1733, he remained at Amsterdam for the rest of his life, and died there, 24th March, 1744. He had meanwhile paid another visit to England in 1740. His edition of the Greek New Testament appeared at last, at Amsterdam, in two volumes, folio, in 1751 and 1752. Notwithstanding many errors by which it is disfigured, this edition (now become very rare and highly prized) is the best text which an exigent critical student. The first volume of an intended reprint of it, in 4to., corrected and improved, appeared at Rotterdam in 1831, under the care of the learned J. L. Oosterhoff, who prevented its being continued. The portion published contained only the Prophets. There is also a previous reproduction of the Prolongmena at Halle, in 1794, under the care of Dr. John Solomon Semler. Two epistles attributed to Clements Romans and Corinthians were built on, and the New Testament, from a Syriac MS., have been proved by Lardner to be spurious.

WETTER. [Sunda Islands, Lesser.] WETTEIAN, LAKE. [Sweden.]

Wexford being a county, or considered a part of a whole in the government of Coblenz in the Prussian Rhine province, is situated in a romantic country on the banks of the Lahn, over which there is a stone bridge, and which is joined by the Dill and the Wetzbach. The town is surrounded with walls, and the entrance is flanked by a tower, and on the side of a hill, on ground so very uneven as to be hardly accessible to carriages. There are three Protestant and two Roman Catholic churches, of which the cathedral, dedicated to St. Mary, is a very spacious and fine edifice, with windows constructed by a French architect. The public establishments and institutions are, an hospital, a united Roman Catholic and Lutheran gymnasium, a school of industry, and a Bible Society. The houses are built in the old-fashioned German style. The population is estimated at 26,800. In the year 1806, 1000 Roman Catholics, and 100 Jews. The inhabitants have some manufactures of stockings, gloves, and tobacco, some tanneries and oil-mills, and a trade in iron. Wettern was formerly a free imperial city, and from 1993 to 1906, the seat of the imperial chamber, or supreme court of appeal of the empire. By the Congress of Vienna it was assigned, in 1815, to Prussia.

(Müller, Geographisches Wörterbuch des Preussischen Staates; Hauss, Handbuch, vol. iv.; Stein, Geogr. Lex. i.)

WEXFORD, a maritime county in the province of Leinster, in Ireland, bounded on the east by St. George's Channel, on the south by the Atlantic Ocean, and on the west, north-westward beyond a few small islands, by the county of Waterford, Kilkenny, Carlow, and Wicklow. The greatest length of the county is from south-west to north-east; and its extreme extent, measured in this direction, from the promontory called Point Hook, on the east side of the entrance to Waterford harbour, is about 54 miles. Its greatest breadth from east to west, between Greencastle and the estuary of the Suir, in Waterford harbour, is about 28 miles; and travelling northward from this line, the breadth does not diminish materially, excepting where the coast is indented by Wexford harbour, to point a little north of Newtownbarry, beyond which it contracts suddenly, so that the north-eastern extremity of the county forms a mere promontory, little more than 12 miles across, between the sea and an island, called St. Mary's or Old Head. The total area of the county of Wexford, according to the Ordnance Survey, is 576,589 acres, 22 poles (rather more than 900 square miles), of which 572,919 acres, 3 rods, 39 poles (about 837 square miles), consists of land, and 3,670 acres (about 5,937 acres) of water. The population, in 1831, was 192,713, which gives an average of about 284 persons to each square mile. According to the evidence laid before a select committee of the House of Lords, upon Irish Tithe, in 1831-2, the figures in which differ slightly from the above, Wexford stands fourteenth in the list of Irish counties for superficial extent, but was then the ninth for absolute extent of land under cultivation, and nineteenth for amount of population. In 1841 the population was 202,953, which gives an average of nearly 268 persons to each square mile; and in the year the county stood seventeenth for the actual amount of population. This is the same as that of the English county of Warwick, but the population in 1831 was less than three-fifths that of Warwickshire; Wexford, the county town, is rather more than 70 miles south of Dublin by a direct line; in about 52° 23' N. lat. and 6° 27' E. long. The range of the county of Wexford is from about 52° 6' to 52° 48' N. lat., and from about 6° 8' to 7° 1' W. long.

Coast-line.-Owing to the position of Wexford at the south-east corner of Ireland, the land must be quite irregular, its coast line being cut off in straight and abrupt angles, and with many promontories, which are occasionally interrupted by very few prominent points. Near the centre of this, which is sometimes called Kilbride bay, a small inlet at Courtown has been formed into a floating harbour for small craft, by the construction of two rough piers. From Courtown to the River Point, on the north side of the entrance to Wexford harbour, a further distance of between 16 and 17 miles, trending rather more to the west, the coast-line is unbroken by any entrance suitable for ships. Indeed the whole line of coast from Arklow, which lies about five miles to the north of the northern boundary of Wexford, to Wexford harbour, presents no opening which can afford shelter from foul weather, except to small craft; and the danger to shipping is great in this part of the coast. It is estimated that the shore is on the average six miles from the entrance of the harbour, which contracts so suddenly opposite the town, as to be crossed by a bridge 1571 feet long, a portion of the roadway of which is made movable, to allow the passage of masted vessels into the inner portion of the harbour, which again contracts, though only for a short distance, to the width of about two miles. A bank of shifting sand outside the entrance to the harbour has been removed for some years; and it leaves so little depth of water that the entrance to the harbour is injurious for anything beyond the size of fishing-boats; and the navigation of the interior is both intricate and shallow. Several remedial measures have been suggested, but none as yet acted upon. The harbour contains a few small islands, called the Saltee islands, the Little Ireland, and Great Island, in both of which there are remains of monastic buildings. From Rosslare Point to Greencastle Point, nearly seven miles in a south-easterly direction, the coast forms another bay, called Greencastle Bay, and opposite the point, about three furlongs from the shore, is a detached rock called Carrick Beacon. From this point, for rather more than five miles, the coast again trends a little westward in an irregular line to Carnmore Point, which forms the south-eastern angle of the county, and of the whole of Ireland. Opposite to this portion of the shore, about seven miles south-east of Greencastle Point, is the Tuscun rock, the position of which is marked by a revolving light, and by a bell in foggy weather. On the south-west hand of the county, from Wexford harbour, a distance of between nine and ten miles in a straight line, is a shallow bay, into which two considerable lakes, called Lady's Island Lake and Tassumahin Lake, open, the former by an artificial communication which is about a mile long. The larger lake is separated from the sea; this lake is remarkable for the circumstance that, while it receives several small rivulets, it is supplied with water from the sea, which communicates with it, and supplies the smaller lake, which is only about half a mile long, and the smaller is about half a mile wide; both contain some rocky points, to which the larger lake is about one-third of the larger island comparable.
Lewis states that, according to a late return from the incumbent of the adjoining parish on the mainland, the Saltee islands are considered to belong to the county of Tipperary, though the smallest of the two, which is nearest to the mainland, a ridge of rocks called St. Patrick's Bridge, having only from seven to ten feet of water at low tide, extends to the adjoining shore, affording an exceedingly dangerous obstacle to the navigation. Several small sand-banks occur in the vicinity, and a floating light is stationed a few miles south of Great Saltee island. Westward of Crossfarnoge Point is Ballyteige Bay, and the coast inclines a little northward as far as the entrance to Bannow Bay, about nine miles west of the point, where a rich coalfield occurs, along which the line, which is a small island, from the sea. Bannow Bay is an irregular shallow inlet which runs about four miles inland, in a north-easterly direction, to Clonmines, and it has a small island, called Bannow island, at its mouth, from which for a distance of eight or nine miles the coast runs in an irregular line to the south-west, terminating in Hook Head, which is the extreme south point of the county. Along this part of the coast are the small dry harbour, used by fishing vessels, called Fethard Bay, the prominent points Bagbin Point and Baginbun Head, where the shore is rocky and precipitous, and several small bays of little importance. At Hook Head is a lofty lighthouse with a stationary light, situated so that the other lights are easily visible. This coast, which is exceedingly rugged and dangerous, and has been the scene of many shipwrecks. Immediately after doubling this point the shore turns back in an easterly direction, and the entrance to the south-eastern boundary of Waterford harbour, and reducing Hook to a narrow peninsula, which, for a distance of three and four miles, nowhere exceeds one mile in width. From Templetown bay, about four miles from Hook Head (within Waterford harbour), the coast runs again towards the west for about five miles, to the estuary of the Suir. The Waterford coast of Waterford harbour is indented by numerous small bays.

**Surface, Geology, Hydrography, and Communications.**—The county of Wexford is in a great measure cut off from the rest of Ireland by natural boundaries. From the extremity of its sea-coast in Waterford Harbour, the estuary of the Suir, and the river Barrow, the lower part of which is called the River of Ross, which flows into it, forms the boundary of the county for a distance, in a straight line, of about 16 miles, to the point of junction of the counties of Carlow, Wexford, and Kilkenny. For 12 or 13 miles farther, in a north-easterly direction, the boundary is marked by the stream that flows from the Mountain and Mount Leinster, the former of which rises in several points, along the boundary-line of the counties of Wexford and Carlow, to elevations of from 1320 to 2200 feet above the level of the sea at low-water, while the other is marked by the stream that flows from the elevation of Cassidy, in the county of Wexford, to the north of the town of Wexford, and also considerably to the south of the forth Mountains. Granite appears about Carnsore Point, in the south-east, and at the Carrick Byrne and Camarosa Hills; and blocks of that substance are frequently seen among the stones at the mouth of the sea, and the whole length of the coast. Beds of greensand also occur in a few places among the clay-slate, which, near Enniscorthy and in several other places, is much intermixed with quartz rock. The principal ranges of elevated land however consist of clay-slate, and good sands are quarried near Newtownbarry, and in other parts adjacent to the granite chain. A black and slightly carbonated clay is found near Enniscorthy, and has been mistaken for coal. That part of the county which borders on Waterford harbour consists principally of clay-slate, with which the nearby valleys are surmounted in two or three places with a cap of sandstone. From Templetown Hill, near the Hook promontory, such a cap declines until it underlies a tongue of flint limestone, which extends to the extremity of Hook Point, and is arranged in thin strata dipping at an angle of 4° to 8° towards the south. This limestone contains numerous bi-valves and corallites. The sandstone rocks form the precipitous coast about Bagbin Point, and appear in several places characterized by the presence of a curious granular rock, which is called Hook Point stone, in addition to the limestone at Hook Point, some is found a little south of Wexford town, and also at Duncormuck, above the middle of the southern coast. The Saltee islands are clay-slate sur-
mounted by beds of sandstone. Lead has been found and worked at Carlow or Carrig. Silver was formerly raised near Clonmines, where there are the remains of an antient mine, and galena has been found there. Copper ore exists at Kerlogue, near Wexford, and it is supposed to have been worked formerly; and plumbago and sabastos have been found near Carlow. The horns of the elk, or horse-deer, and bones of the moose-deer have been discovered in the alluvial districts on the east and south, where marl occurs; and about seven years ago a perfect fossil specimen of the Cerces Megaceros, or gigantic deer of Irelan, of extraordinary dimensions, was found at Ballyhuskard, near the bog of Itty.

In climate, those parts of Wexford which lie open to the sea are milder in temperature than the antient counties of Carlow and Kilkenny. Snow seldom remains on the ground, and the mildness of the climate may often be carried without interruption, while lands ten miles inland are covered with snow or locked up with frost. The southern district is exposed to storms in spring and autumn, and to heavy rains in winter; but the climate is generally more favouring. The rain falls in moderate amounts, and the harvest is at least as early as in those Welsh counties which lie more southerly on the opposite side of the Channel.

The principal communication between Wexford and the interior is the Barrow, which communicates with the Grand Canal. A railroad from Wexford to Carlow was projected a few years since, and the plan was submitted to the Irish Railway Commissioners, but nothing has been done towards its formation. The principal road is the main road of Dublin, which enters the county from Arklow, near its northern extremity, and passes by Gorey and Enniscorthy, and thence along the western side of the Slaney to Wexford; a mail road which leaves this county for Carlow, a few miles north of Newpark, and they may cross the county from Wexford to New Ross. The county is however well supplied with roads in every direction; and the harbours of Wexford and Waterford afford ample facilities for communication by sea. The eastern and southern parts of the county have a deep alluvial soil, abounding with various marls, calcareous sand, and occasionally limestone, but are deficient in peat; and in some parts of the county, where neither turf nor manure is obtained, the soil is of inferior quality. The soil is excellently fit for the growth of wheat, oats, and barley. There are also much hay and straw produced. The Hook peninsula, which is open on both sides to the ocean, and little elevated above it, provides grass, wh erewith to the perfection of sheep, which are exported in great quantities to England. The chief corn-markets are at Wexford, Enniscorthy, and Castlebridge, Wexford being the port through which the trade of the other two passes. New Ross also exports the like produce to a considerable extent, while Wexford and Waterford export wool and flax to Bristol, Liverpool, &c.; and cattle, pigs, and poultry are sent to England by steam-boats from the same ports. For statistics of the produce of Wexford see the next article.

DISTRIBUTION OF LAND.

The exception of parts of two parishes which belong to the diocese of Dublin, the whole of the county of Wexford is in the diocese of Ferns, and the ecclesiastical province of Dublin. It is divided, for civil purposes, into eight baronies, one of which is subdivided into two portions; their names, positions, respective areas, and population according to the returns of 1801, are as follows:

The county contains the ancient episcopal town of Ferns; the county-town of Wexford; the market and post towns of New Ross, Gorey, Enniscorthy, Newtownbarry, and the disfranchised borough of Fethard; and the post towns of Arbourthorn, Ballymoggog, Camolin, and Tagoat, the last of which was antiently a borough, as were also Clonmines and Bannow. Of the above places Ferns, Wexford, Enniscorthy, and Clonmines are noticed elsewhere.

Barrow, or River of Ross, about 11 miles in a straight line, or 14 or 15 measured along the windings of the river, from the point where it enters Waterford harbour. At high tide the river is navigable up to New Ross, about 500 miles above. At low water there is sufficient depth for vessels of 200 tons; and above the town the river is navigable for barges as far as Athy, where it communicates with a branch of the Grand Canal. The parish lies chiefly in the barony of Barrow, but partly in that of Shels- bury, and the town lies about 191 miles west by north of Wexford, on the road between that town and Waterford, and about 71 miles south-south-west of Dublin. The living is a vicarage, in the diocese of Ferns, forming, with several adjacent rectories, the union of New Ross, which is in the patronage of the bishop. The population of the borough and town, in 1831, was 5011, and that of the whole parish of St. Mary, New Ross, was 7991. The number of houses in the town was 766, inhabited by 1128 families, which gives an average of not more than less than 3 persons, and rather more than 4-5 persons, to each house. The inland traffic of the town was estimated, in 1838, by the Irish Railway Commissioners, to amount to 44,650 tons annually, of which 17,550 tons were carried to, and 27,000 tons from the town per annum. The value of the produce from the town was estimated value of 59,074l., and the imports 26,007l.

On the 25th of March, 1842, the port had ten registered vessels above 50 tons burthen, their aggregate burthen being 1911 tons. The chief articles exported were corn, meal, and flour, wool, blankets, fustian, tobacco, beer, butter, cheese, butter, sheep, and pigs; and the principal imports were of coal, culm, and cinders; fish, and wines. Markets are held on Wednesday and Saturday, and there are several fairs in the course of the year. A charter granted to the town by Roger Bigod, in the 1st year of his reign, was confirmed in 1356, when the town was of the value of 40l. a year, and it was held by a priest being trustees ex officio. The expenditure of the whole, which amounts to 700l. or 800l. per annum, is supplied by bequests, subscriptions, and grand-jury presentments. There are likewise the Vicar's almshouses for three: and the following charitable and public institutions. A Temperance Society, said to be the first established in Europe, was founded in 1829. There are at least two lending-libraries in the town. The town formerly sent two members to the Irish parliament, and now sends one member for the two counties of New Ross and St. Mary's, Old Ross, and the total number of voters on the register, in 1839-40, was 329. The corporation was dissolved by the Act 3 & 4 Viet, c. 106, for the regulation of municipal corporations in Ireland. Immediately east of the parish of New Ross lies that of Old Ross, or St. Mary's, Old Ross, where stood formerly a castle founded by Strongbow, of which the only trace now remaining is an artificial mound upon which part of the building stood.

Gorey, or Newborough, is a market-town situated in the barony of the same name, about 28 miles by road (by road) north of Wexford, and 48 south from Dublin. It sent two members to the Irish parliament, but was disfranchised at the union, when the sum of 15,000l. was awarded to Stephen Esq., as compensation; and it was incorporated in the 17th year of James I., but the corporation was dissolved by the recent act of the 3 & 4 Viet. The name of Newborough was conferred by the charter of James I., but never came into general use. The town contained, in 1831, 325 inhabited houses, 6350 persons, and 650 carriages. The parish, which is also called Christ Church, Newborough, and Killmakilloge, or Kilmeiallge, contains 1437 inhabitants, and is a rectory, which, together with some adjacent rectories, constitutes the deanery of Ferns, in the diocese of Ferns, that of Ferns, in the diocese of Ferns, that of Ferns, in the diocese of Ferns, that of Ferns, in the diocese of Ferns. The bishop of Ferns formerly resided in an episcopal palace at this place, but it was attacked, and the library burned, in 1641, by the parliamentarians, and after being converted into an inn, and subsequently into a barracks, it was at length pulled down. During the disturbances of 1798,

266
There are a Protestant church, a Roman Catholic chapel, and public schools for about 70 children, as well as a Sunday-school. At Baginbun Bay, about a mile south of Fethard, Robert Fitz-Stephen landed his forces on his first invasion of the country, and burnt his ships Bagg and Bunn (whence, according to tradition, the place takes its name). The town is situated in a spacious Roman Catholic chapel in the town, and several others in the district. There is also a meeting-house for Wesleyan Methodists. The market-house is a commodious building, which, formerly used as a corn-house, has been converted into a parish school. A new court-house was built in 1819, and the town has a fever hospital and dispensary, a savings-bank (in which there were 319 depositors in November, 1842), a constabulary police force, a brigade of firemen, and a Sunday-school. The North Wexford Agricultural Association, which has aided the improvement of agriculture and cottage industry in the northern part of the county, holds its meetings at Gorey, and several of its members are engaged in the trade of manufacturing and marketing wool. The town contains various small manufacturing establishments. Epiphany and Midsummer quarter-sessions for the county are held here, and petty sessions every fortnight, the latter being held to the north of the town. The neighborhood is picturesque, and contains many elegant villas.

Newtownbarry, or St. Mary's, is situated on the south bank of the river Clody, close to its confluence with the Slaney, in the barony of Scarawalsh, close to the northern boundary of the county. It is about 22 miles north-west from Wexford, and 50 miles south of Dublin. The parish contained 3592 inhabitants in 1831, of which 1430 were in the town, which had at the time 233 inhabited houses and 264 families. The living is a rectory, part of which is a patronage of the diocese of Ferns. The Church of Ireland is attended by the Irish inhabitants, and a Roman Catholic chapel and two public schools; a dispensary; a constabulary police-force; and fortnightly petty-sessions. The place derived its name, which was originally Threaq Munno, or 'The House of Munno,' from St. Munno, who founded an Augustinian monastery in the sixth century, to which the origin of the town is attributed.

Bannow was also formerly a corporate town and parliamentary borough, although its corporation has long been extinct, and it was disfranchised at the Union, when 15,000 votes were purchased for the Union, and 25,000 for the borough. It contains 1481 persons in 1831, lies on the east side of Bannow Bay, a little north-east of Fethard, in the barony of Barony of Fethard, which extends to the sea, are supposed to be occupied by the ruins of the town, which is so completely buried that it has been called the Irish Herculaneum. A lead-mine was formerly worked in this parish, and silver is said to have been raised there.

The mere post-mortem law of the county, as far as it extends to Arthirstown, or King's Bay, in the parish of St. James, and barony of Shelburne, 94 miles south-east by south from New Ross, and 80 miles south by west from Dublin, containing about 170 inhabitants. It lies on the north side of Wexford Harbour, and is about the mouth of the Stour, and has a small trade. In this village James II. is said to have spent his last night in Ireland, after the battle of the Boyne. In the immediate vicinity is Duncannon fort, from a rock to the north of which was embarked King James upon his flight from England, the parish of St. Iberius, and barony of Forth, 8 miles south-south-east from Wexford, at the northern extremity of Lady's Island lake, containing 160 inhabitants.

Clonegal lies chiefly, if not entirely, in the county of Carlow, in the parish of Mayoabamb, which extends into Wexford, in the barony of Scarawalsh. It is a place of little importance, containing 446 inhabitants.

Camolin is in the parish of Donaghmore, and barony of Scarawalsh, situate on the river Ban, and in the road from Wexford, New Ross, and Gorey. It contains 170 inhabitants. It lies on the north side of Wexford Harbour, and on the banks of the Stour, and has a small trade. The county of Wexford sent eighteen members to the Irish parliament—two for the county, and two each for the boroughs of Wexford, New Ross, Gorey, Emniscorthy, Taghmon, Fethard, Clonmines, and Burkes. In the Union with England, it sent to the British parliament—two for the county, which are elected at New Ross and Wexford, and one for each of the boroughs of Wexford, New Ross, and Gorey.

The number of county voters on election in 1838, was 650, of whom 160 were Cahetsheachers. For legal purposes the county is divided into the Leinster circuit; the assizes are held at Enniscorthy, and in general sessions the peace are held at Enniscorthy, and at the times for the trial of the county and magistrates, 2153 inhabitants, of which only 3230 were to the town, or rather village, in 50 houses. A branch of the coast-guard department is stationed here, and a small trade is carried on from the port. The harbour was constructed by government in 1798, and is capable of receiving four small sloops. The town was the capital of the barony of Fethard, but the corporation is now extinct. It sent two members to the Irish parliament, and 15,004, was paid as compensation upon its disfranchisement at the Union.
local government is vested in a lieutenant, 16 deputy-lieutenants, and subordinate magistrates. In military ar-
rangements the county is in the Eastern district, and it con-
tains barracks at Wexford, New Ross, and Duncannon.

The effective strength of the constabulary force of the
county, on the last day of January, 1841, was as follows:—1
county inspector (second-rate); 7 subinspectors (3 first-
rate, 1 second-rate, and 3 third-rate); 8 head-constables
(1 first-rate and 7 second-rate); 38 constables; 189 sub-
constables (1 first-rate and 23 second-rate); and 60
horses. The total expenditure upon the constabulary
force of the county, in the year 1840, was £2,509d. 12s. 8d.

The county of Wexford is included in the Carlow distric
Lunatic Asylum, and the number of patients from it in the
year 1840, was 50,652; the number of patients in the hospitals at the end of
that year was 112, but beds were provided for 265. The
total income of all the establishments, in 1837, was
£5654. 16s. 14d., of which 2945s. 6s. 4d. was provided by
county precity seigneur, 1792. 1s. 3d. by subventions from the
Roman Catholics, and the remainder by Treasury grants, fines, &c.

The grand-jury presents of the year 1840 amounted to
£2,396s. 0d. 6d., distributed as follows:

Total: £4,239 0 6

The total amount of county cess levied in Wexford in
the four years ending 1839 was £492,764; and the amount for the last
year of that period being £37,547.

Population, Statistics of Crime, &c.—The population
of the county of Wexford has been calculated, at various
times, as follows:—

<table>
<thead>
<tr>
<th>Year</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>1792</td>
<td>66,804</td>
</tr>
<tr>
<td>1812</td>

| Families chiefly employed in trade, manu-
  facture, &c.   | 6,155      |
| All other families | 5,236     |

Of the persons engaged in agriculture, 3978 were occu-
pers engaged in the fisheries, 10,937 in the coal
labourers, and 15,321 labourers. The number of labourers
employed in manufactures and in making manufacturing
machinery was only 109; the persons employed in retail
trade or handicraft, as masters or workmen, 7934; other
labourers, employed in labour not agricultural, 2176; cap-
itals, bankers, professional and other educated men,
1306; male servants 20 years of age and upwards, 693; male
servants under 20 years of age, 639; and female servants,
747; the returns of 1841 no more than a quarter of
which has yet been published; from this it appears that there
were in that year 97,918 males and 104,115 females. The
number of families was 34,718; the number of inhabited
houses 33,507; of uninhabited houses 1108; and of houses
in progress of erection 103.

From the returns of the Commissioners of Public instruc-
tion in 1831, we learn that as in other counties, 42 women
found themselves residing in Wexford, which was Roman
Catholic. The returns for the county are the most reliable
of any; and it is not likely that in Wexford, which was the
centre of a permanent settlement. Camden mentions
another popular designation of the county, as 'the rough
county,' or County Rough; and the northern portion of it
was included in Hy Kinselagh, afterwards called
Weskagh, the territory of the MacMurroughs, who had a
favourite residence at Ferns. Wexford is distinguished

History and Antiquities.—In the time of Ptolemy the
greater part of the present county of Wexford was in-
bhabited by the Menapii, whose chief town, Menapia, sup-
posed to have occupied the site of the present town of
Wexford, was situated on the river Modounus, now Wex-
ford, and was the only town of importance in the
region. The Menapii were a tribe of the ancient Menapii.
The ancient inhabitants are sup-
posed to have derived their origin from the Menapii
of Belgic Gaul, possibly through the Belgae of Britain, and
to be called the Irish menapii. The whole of the
county, which the town of Wexford is called,
was the Menapii, was called

Hook. The country was anciently styled Cotchig,
(a name which appears to be reserved in that of the
Menapii, Menapia), and the

name is said to be derived from

containing the first landing-places used by the English, when, in 1170, or according to other authorities, 1169, they invaded Ireland under the command of Robert FitzStephen, under the circumstances mentioned in the article Ireland, vol. xiii., p. 21. The English army landed at Barginbun, near Fethard, and shortly afterwards attacked the Dunes at Wexford, on which place, after a contest of four days, they obtained possession. MacMurrough then confirmed a grant which he had previously made of Wexford and some adjoining parts to the English adventurers, whose settlement in the country so alarmed the French and the Irish as to induce them to attempting to drive out MacMurrough and his English allies. A treaty was made between the contending parties at Ferns, in which a secret article for the expulsion of the English was inserted; but the invasion was driven off, and the English, after a month's occupation, were driven out of the town, and their conquests were soon generally extended by the prowess of Richard de Clare, surnamed Strongbow, who married Eva, the daughter of MacMurrough, after whose death, in 1172, he became Lord of Leinster, a title which was confirmed to him as a palatinate by Henry II. of England, when he visited Ireland shortly after. The English king retained the town of Wexford for a time in his own possession but soon conferred it upon Strongbow. Wexford was formed into a county by King John in 1210, and in 1215 it was formally exchanged by John, King of England, and William le Marsichal through his marriage with the daughter of Strongbow. On the extinction of his male line, his possessions were divided among his daughters, and, owing to frequent changes of proprietorship and the prevalence of the bankruptcies and seizures formerly existing in Ireland, the state of great confusion, and consequently a considerable part of the county was seized by one of the Kavanaghs, who, early in the fourteenth century, assumed the title of MacMurrough, and declared himself king of Leinster. The right was confirmed by John Esmond, Bishop of Ferns, who had been deprived of his episcopal dignity by the pope in 1349, maintaining himself by force of arms in his castle at Ferns. He was at length, with considerable difficulty, compelled to enter into articles by which he was to keep the peace. From the year 1474 to 1557, when the Irish possessions of the great absentee lords were vested in the crown, the county was divided into two separate jurisdictions: the Liberty, which was governed by the family of Thirlot, Earl of Ormond; and the Great Island, in whose possession the lands formerly belonging to William le Marsichal bad descended; and the Cross, or Church lands in the county, over which a sheriff was appointed by the king. During this period two members of parliament were elected for the Liber and Great Island, but from 1560, under Ormond, were defeated in an attempt upon New Ross in the early part of the war, and subsequently Dunmore town was taken by the Catholics. In 1648 the whole country was reduced to subjection to the Parliament of Dublin, and all the leaders of government, but one, were driven from the country. In the rebellion of 1798 the country enjoyed almost uninterrupted tranquillity, but it became the chief seat of that insurrection, and the scene of many severe conflicts. The county was placed under martial law in the month of April in that year, but no military force was actually sent there until hostilities had broken out elsewhere. It was suspected that the secret organization called the Society of United Irishmen had extended into Wexford, and the harsh conduct of the military in endeavouring to force the suspected parties into a confession of guilt, together with the burning of a chapel at Boulavogue, in the parish of Kilcormuck, exasperated the people, and led them to assemble in arms at Oulart and Kilmeathomas. They were soon dislodged from the latter place by Dunleary, which was demolished, and, as the result of the dispersion of the inhabitants of Wexford, but they appeared to have been not without parallel among the loyalist soldiers. The rebels at length, having chosen for their general Beauchamp Bagnal Harvey, Esq., a Protestant gentleman who had distinguished himself as a friend of the people and an opponent of the despotic measures of government, attacked New Ross, but were repulsed with much loss after ten hours' fighting. Harvey was soon afterwards superseded by a Roman Catholic priest named Roche. The royal forces, having collected their strength from various quarters, then made a simultaneous attack upon Vinegarhill, and forced the insurgents to retreat. Wexford was after this retaken, and many of the insurgents suffered capital punishment; and this complete defeat of the main body of rebels put an end to the insurrection in this district, excepting in the case of a few small detached parties.

The county of Wexford, especially the southern part, abounds with antiquities of Danish, Saxon, and Norman origin, though comparatively few can be assigned to a period prior to the arrival of the English in the country. Tombs, mounds, or ruins, are found in the neighbourhood of Enniscorthy, at Salville or Mountbeque, near Duncormacke, and many other places, of considerable size, near Dunbrody, and one near New Ross. Of smaller raths, which are numerous in the southern baronies, one of the most perfect is at Ballytrent, and is now laid out as a pleasure-ground. There are remains of monasteries at Wexford, Enniscorthy, St. John's, south of Enniscorthy, Ferns, Dunbrody, near the confluence of the Suir and the Barrow, Ross, and Clonmines. Of other ecclesiastical edifices, Tinvery Abbey, near the Bantry Bay, was formerly converted into a dwelling; and Colcough, Ballyharry, and Clonmore are turned into parish churches; and the ruins of Glascarrig are partly used as a farm. There are ruins of an ancient chapel, called St. Vaughn's, near Cramorne. Religious houses were also formerly numerous; of these, the only one whose traces now remain. Ruins of castellated buildings are numerous. At Wexford are the remains of White Castle, near the entrance of the harbour. Carrig Castle, on a rock by the Slaney, lies two miles north-west of Wexford; and among the same districts there are two other, both on the heights of Barmston. There are also ruins of castles at Ferns, Enniscorthy, Mackmime, black castle, on the Slaney a few miles below Enniscorthy, Cuanlan-na-Blathie, or Buttkavans, near Castle; and Castle Head. These, and the other sepulchral rock, and Kilhile castles, in the same neighbourhood. At Ballykeroge are considerable remains of a castle founded by Roger de Sutton, and near the same place are ruins of castles at Stoketown, Aldermaston, Friest's Haggard, and the Great Island. At Muntragh to a hill overlooking New Ross, are the remains of a castle; on the Hook peninsula are ruins of Stude and Houseland castles, and, on its extreme point, of an old fort called Hook tower, now converted into a light-house; and on the Bantry Bay, near where the port is, are some ruins. The very numerous indeed are the remains of this character, that it is observed, in the work of Mr. and Mrs. S. C. Hall, referred to above, that, as evidences of the power of the Anglo-Norman intruders, as well as of their peril in the case of brave the vikings, is not to be despised; but there are no fewer than six score of their castles and towers, now in ruins, in the four southern baronies alone—in Fethard thirty-one, in Ballytrent twenty-seven, in Shelburne thirty-seven, in Shelmalier twenty-five. Among the military remains not mentioned above is Strongbow's fort or camp, near Dun-cormack castle, on Barginbun Head, where intrenchments are yet visible. Of more recent objects of interest in the county may be mentioned a great pile of stones at Wicklow Gap, near its northern extremity, marking the spot where those who fell in a sanguinary conflict between the insurgents and the royal troops, in 1798, were buried. It is the custom for every passenger to add a stone to the heap, and offer a prayer for the souls of the deceased.
extend more than about a third of a mile in a south-western
direction from the harbour. There are six parishes in the
town, the aggregate area of which, according to the Or-
dinance Survey, is 69 acres, 1 rood, 27 poles. The popu-
lation of the entire town and borough, in 1831, was 10,672,
and the number of houses about 1820. The town is gene-

erally well built; but the streets are narrow, partially and
but indifferently paved; supplied with water partly by
pipes, partly by wells, and partly by a public conduit in the
north-eastern part of the town. The streets are criss-crossed
by numerous quays extend along the harbour the whole length
of the town, towards the centre of which the otherwise nearly
straight line is broken by the Crescent Quay, which is
indented in a semicircular form. Near the opposite
Concourse, and across the quay from the quay, is a kind of
breakwater, called the ballast quay or bank, formed by
the ballast deposited there by ships which frequent the
port. The haven contracts abruptly opposite to the
northern end of it, and is called the timber bridge, con-
structed entirely of American oak, at a cost of 17,000l., by
Emanuel Cox, an engineer from the United States, who erected
the several other extensive bridges in Ireland, was built in 1794-95. The width of the opening
crowned is 100 feet, and the 335 feet bridge (exclu-
sive of 6000l. for the repair of that length; but as it had fallen much into decay, it was
some years since repaired, or rather reconstructed, at an
expense of 6000l. In its present state it consists of two
causeways, projecting 630 feet and 188 feet from the north-
eastern and south-western banks of the quay. An old
timber bridge of 733 feet, supported by 23 piers of the
same material, and having a drawbridge for the passage of
masted vessels into the inner harbor, which expands considerably a little above the bridge. The toils of Wex-
ford and the necessities of the coast require that port is considered a good nursery for seamen, and has
many apprentices in the merchant-service. It possessed, on
the 25th of March, 1842, 69 registered vessels of upwards of 50 tons, their aggregate tonnage being 7114 tons; and
the customs revenue returned in the year ended 30th May
1837 was 11,11d. in the previous year they were 8409l. 3s.
4d. The export trade was estimated, according to the
returns published by the Irish Railway Commissioners, to amount to 12,130l. in 1839, and 12,617l. in the
year 1842. More than one-half (in value) of the exports consisted of corn, meal, and flour: butter was esti-
mated at 54,000l.; oxen at 36,000l.; sheep at 15,000l.;
and swine at 12,000l. Of the imports, 150,000l. is set down, as being the cost of the port, and 10,000l. (exclu-
sive of 6300l. for British refined sugar) 26,100l. for coal,
corn, and cinders; 19,400l. for cast-iron; and 19,000l. for
wrought-iron and hardware: the remaining items com-
priised chiefly manufactured goods, and various articles of
decorated plate. The cargo of vessels engaged in regular
communication with Liverpool and other places, and
the Slaney affords navigable communication with Ennisworth and the interior of the county. The shipping
interests of Wexford have been promoted by the formation,
within the last ten years, of a bank and also by the
establishment of the Bath Hotel, in which the Accts. of
Capt. Vallotton was killed. A monumental obelisk on the
Windmill Hill commemorates this event. During the
insurrection of 1798 the town was evacuated by the garrison,
in a panic occasioned by the defeat of a detachment of
royal troops marching from Wexford to assist the insurgents, and the rebel
troops immediately made it their head-quarters. They retained
possession from the 20th of May to the 21st of June, during
which time they beheaded ninety-one prisoners on the
bridge; but after the defeat of the insurgents at Vinegar-
hill the town was reoccupied by government forces under
James II. gave one at a later period, but it was annulled
after the Revolution. Wexford is one of the towns whose
portions were dissolved by the act of the 3rd and 4th of
Victoria. The town sent two members to the Irish
parliament, and now sends one to that of Great Britain.
The number of registered voters in 1839-40 was 405.
(Ordinance Survey of Wexford; Lewis's Topographical
Dictionary of Ireland; Parliamentary Papers; &c.)

WEY. [WIGHTS AND MEASURES.]

WEY. [WIGHTS AND MEASURES.]
WEYERMAN, JACOB KAMPO, a Dutch fruit and flower painter, born at Breda, in 1678, notorious for his bad character and scandalous writings. He wrote a set of lives of Dutch painters, which, according to Van Gool, are full of calumnies; and Descamps says of him, "Ils remplis ses pages d'innombrables calomnies, d'impietés, et de calomnies." This work is entitled 'Leverlijdenissen der Nederlandische Konstschikters en Schildersena." 'Sgravenhage, 1729, 4to.

In one of his scandalous writings he attacked the Dutch East India Company; and in 1739 he was condemned to perpetual imprisonment at his own cost, in which he died in 1747.

He learnt painting of Ferdinand van Kessel, and had great skill in his style and great facility in writing; he however neglected his art and abused his abilities, and, according to all accounts, appears to have been a thoroughly bad man in every respect.

(Van Gool, 'Schouburg der Nederlandische Schilder, &c.; Descamps, 'La Vie des Peintres Flamands, &c.)

WEYMOUTH and MELCOMBE REGIS, in the Dorchester hundred, in the county of Somerset, is a seaport, and borough, which was distinguished as a market and place of resort, in the reign of Henry VIII., from the site of its bathing-place, known as the Great Sea Bath, which was in operation in the reign of Edward IV., and afterwards called the Backwater, a large pond, which was of considerable extent, and formed a body of water of considerable depth, with an arm of the sea, and a part of the estuary of the Wey, known as the Backwater. The present Backwater is a pond of considerable extent, and is a favorite resort for the bathing and boating parties of the town, and is connected with the sea by a channel, known as the Channel Stream, and with the mouth of the Wey by the Backwater. The Backwater is a body of water of considerable extent, and is a favorite resort for the bathing and boating parties of the town, and is connected with the sea by a channel, known as the Channel Stream, and with the mouth of the Wey by the Backwater. The Backwater is a pond of considerable extent, and is a favorite resort for the bathing and boating parties of the town, and is connected with the sea by a channel, known as the Channel Stream, and with the mouth of the Wey by the Backwater. The Backwater is a pond of considerable extent, and is a favorite resort for the bathing and boating parties of the town, and is connected with the sea by a channel, known as the Channel Stream, and with the mouth of the Wey by the Backwater.

WEYMOUTH Proper is described as having the appearance of an old fishing-town, with mean-looking houses and narrow streets. Melcombe is situated on a tongue of land between Weymouth Bay and the Backwater, very narrow on the north-east, but becoming wider towards the harbour, where the width is about a third of a mile; the ground on which it stands is low, a considerable part of it having been reclaimed from the Backwater by embankments, which were afterwards converted into a park. There is a pond, which is called the Esplanade, extends nearly a mile, with a gradual slope towards the shore; the ranges of houses which face this Esplanade are handsome, and many of them large; most of them are occupied by those who resort to the town as a summer resort, and who have become adapted, the sand being smooth and firm, and the slope very gradual. The houses in the back part of the town are inferior and the streets narrow.

Weymouth had been a declining place for many years from various causes, but chiefly perhaps in consequence of the rivalry of Poole, till it was brought into requisition as a bathing-place, about 1783, by Ralph Allen, of Bath. The duke of Gloucester went there in 1780, and had a house built for his residence. George III. paid his first visit in 1788, and King George IV. in 1789, and royal visit, and others frequently. The climate is very mild, Weymouth Bay being sheltered to the north by surrounding hills, which have a gradual slope to the south towards the beach. There are assembly-rooms, a theatre, two national schools, Pannier, Lancasterian, and two churches, one of which is in Weymouth, which is a curacy attached to the rectory of Wey Regis, and there are places of worship for Independents, Baptists, Quakers, and Methodists. In the savings-bank the number of depositors, November 20, 1839, was 8159, with which sum on which interest is allowed is 14s. 6d. Ship-building is carried on, and rope-making; but little is done in any other trade.

The number of vessels above 50 tons burthen belonging to the port of Weymouth, in 1840, was 56, the aggregate burthen to all accounts being 57 tons. The gross receipt at the customs-house, in 1839, was 12,907l. 7s. 7d.; in 1840 it was 14,727l. 11s. 4d. The trade of the port of Weymouth, in 1833, was—

Previous to the Municipal Reform Act, the corporation consisted of a mayor, an indefinite number of aldermen, two bailiffs, and twenty-four principal burgesses. The Municipal Reform Act divided the borough into two wards, with six aldermen, and a council of eighteen. The number of burgesses was reduced to twelve, each electing 210l. in 1837, or 55s. 8d. 61s. 319. The total expenditure of the borough in 1840-41 was 2165l. 3s. 10d.

Weymouth and Melcombe Regis. Before the Reform Act returned four members to the House of Commons. The right of voting was in the corporation, the members of the two houses, and the freeholders. There were no freemen. The number of voters reckoned to be about 2000, but the largest number of electors who polled at any election for thirty years previous to 1831, was 745. The borough now returns two members to the House of Commons. The number of electors on the register in 1833-4 was 617, of whom 536 were 10l. householders; the number on the register in 1839-40 was 600, of whom 507 were 10l. householders. The population of the borough, in 1831, was—

- Chapelry of Weymouth: 3299
- Parish of Melcombe Regis: 5126

7525

In 1821 the population was 6692. The number of houses, in 1821, was 1213; in 1831 the number was 1465. The population within the limits of the parliamentary borough in 1831 was 8096.

Weymouth is 128 miles from London by road. There is no direct mail from London, but a cross-mail from Dorchester, which is 5 miles north of the town. Weymouth is an ancient place: it is mentioned in the 'Domesday Book,' and was afterwards a place of some naval importance. In 1347 it furnished 20 ships and 264 men towards the armament destined to attack Calais. In 1588, when the Spanish Armada sailed to attack England, six ships of the English fleet belonged to Weymouth. During the civil war under Charles I., Weymouth was alternately garnished by the royalists and the parliamentarians till 1644, when the parliamentarians obtained possession which they held till the close of the war. In the reign of Charles II. Weymouth was greatly injured by a fire, and 3000l. was collected in 1673 by a brief, towards repairing the damage which it had sustained. The earliest charter known to have been granted to Weymouth was one in 1262, by the prior and canons of St. Swithin, Winchester, to whom the manors of Weymouth and Melcombe had been granted by Henry I., a grant which was confirmed and extended by Henry II. A grant of certain liberties and privileges was made to Melcombe Regis by a charter dated 27 May, 8 Edw. I., and followed by another, dated 22 Jan., 11 Edw. II.; by one dated 3 Nov., 2 Edw. III.; and by one dated 16 May, 2 Eliz. The union of the two boroughs was by an act of parliament, dated 2 April, 6 Eliz. July 1, 14 James I. Another charter of incorporation was granted; and to remedy certain defects in this charter, an amending and explanatory charter was obtained, 19 August, 21 Geo. II. In 1822, in consequence of the diminution of the number of principal burgesses, it was determined that the corporation might be legally dissolved, to avoid which a new charter was obtained, 25 May, 44 Geo. III., which was the governing charter of the borough till the Municipal Reform Act in 1835.

(Municipal Corporations' Reports, 1835; Boundary Reports, 1832; Hutchins's History and Antiquities of the County of Dorset; Parliamentary Documents.)

WHALE FISHERY. {FISHERIES.}

WHALE—Cetacea—order of aquatic mammals with fin-like anterior extremities, the posterior extremities being absent, or rather, having their place supplied by a large horizontal caudal fin or tail, without an external ear, without hair on their external integument, and the cervical bones so compressed as to leave the animal without
any outward appearance of a neck. This order comprises
the largest animated forms in existence; some of the ge-
nera composing it are phytophagic, or plant-eaters; others
are zooplagic, or animal-eaters.

**Systematic Arrangement.**

The cetaceous mammals, whose abode is either in the sea
or the great rivers, resemble the Fishes so closely in exter-
nal appearance, that it is hardly to be wondered at that
not only the vulgar, but even some of the earlier zoologists
looked upon them as belonging to that class. This notion
is kept alive to the present day in the announcements of
the comparative success of those ships which are employed in
the *Whale Fishery*; for not only is it conveyed by that
general term for the capture of whales, but by statements
that they are provided with three *fish*, another with four
*fish*, a third with one *fish*, &c.

If we turn to the sacred scriptures, we find the Hebrew
words *Thau* and *Thannin*, which have been translated by
the words *siren* (the name used by Eneas Grazeus to de-
signate the Fish of whose belly Hercules is said to have
escaped after having been swallowed) and *whale*. *Lycoph-
ron* terms the marine animal that so disposed of Hercules
when he was shipwrecked, *εὔγαρσιν* *κλὼν*, a shark.

The *Delphinus* or *Dolphin* is thus translated from the
Hebrew words above noticed, דְּלֵפִּינוֹס דְּלֵפִּינוֹס, in the 21st verse of the first chapter
of Genesis. The same Greek word is used in the
seventeenth verse of the first chapter of Jonah. In the
book of Job (vii. 12), and in that of Ezekiel (xxii. 2), the
translators used *Fish* and *fish*; in Matthew (xii. 40),
where the swallowing up of Jonah is alluded to, *siren*
is employed.

In Barker's Bible (1615) the passage in Genesis is trans-
lated, 'Then God created the great whales, much the same
as our whaling-men now read in our churches,' And,
God created great whales.

The other passages are translated in Barker's Bible as
follows: — *Jonah* (i. 17), 'Now the Lord had prepared a
great fish to swallow up Jonah: and a fish was in the
bowl,' &c.; in Ezekiel (xxii. 2); 'Thou art like a lion of
the nations, and art as a dragon in the sea, ; in a note, 'or
*whale* is added': —

Matthew (xii. 40), 'For as Jonas was three days and three
nights in the belly, &c."

In the version now used in our churches the passage
in *Jonah* is *verbatim* the same as in Barker; that in *Job
is thus rendered, 'Am I sea, or a whale, that thou seest
set a watch over me? that in Ezekiel, 'Thou art like a lion
of the nations, and thou art as a whale in the sea?'
— that in Matthew is identical with the passage in Barker.

These are merely cited as examples: there are other
passages in the Old Testament in which the words whale
and fish are employed, and the English translators would
be beside the present question to enter into the dis-
cussion whether the whale was meant, or a crocodile,
as some will have it, in the verses above quoted; it is sufficient
for our purpose to show the commonly received opinion
that a whale was a *fish*.

In the index to Pliny's *Natural History* we find the
whales treated as fishes, *Balaenarum piscium consideratio,*
*Balaena piscis, &c.* But, in the work itself the *Balaena* and
*Physeter* are noticed as *Baleae, and a fair account is given
of these animals*. — that in Ezekiel, 'The seventh young
of his ninth book, indeed, is headed ' An splendid piece, an
dormant, ' but in that chapter he expressly states that
neither whales nor dolphins (balaenia ucc delphinus) have
gills, but breathe by means of fistule, or blow-holes, which
appear in the post-nasal region of the brain.'

Aristotle, whose great zoological work Pliny had closely
studied, was certainly aware of the broad distinction
between the whales and dolphins (the position of whose
blow-holes and nostrils) and fishes. Geisser separated the
whales from the fishes, including them in a distinct order of marine animals. Aldrovandi
separated them also, though they appear in the same vo-
lume, the title of which is *Des Piscibus, Libri V.*: *De Cetis,
Libri Unus.* Jolton gives them a separate chapter at the
head of his book *De Piscibus.*

Ray, in his Synopsis *Methodica Piscium* (1713), ob-
serves that the term *fish* is extended, even by the learned
of our country, to the bloodless aquatics, as they were then
termed, *Exangui aquatica, such as Crustacea, Testacea,
and Molnia, or shell-less mollusks. On the other hand,
some, he remarks, not only exclude those *Exangui aquatica,* but also the Cetaceas (*Cetaceum genus, seu Beller-
marina*), contending that no other animals can justly be
termed fishes except those which breathe by means of gills
have but one ventricle to the heart. With the latter Ray
agrees, and expresses his own opinion that, if we speak
properly and philosophically, the name of fish should be re-
stricted to such last-mentioned animals only, and points
out the absence of any relationship of the *Pisces Cetacei*
with the *Mammalia*, says that it is a distinctive mark of
the place where they spend their lives, the external
figure of their body, their hairless skin, and their natatory
progression, the Cetaceae have hardly anything in common
with the true fishes, but in other respects agree with the
viviparous chelicerated.

Nevertheless, that he may avoid dissent from received
opinions and the appearance of paradox, Ray declares
that he will not innovate, but consider the Cetaceous
animals as fishes; and he proceeds to define what a fish is, thus:

the aquatic animal having blood, wanting feet, swimming
with fins, covered either with scales or with a naked,
smooth, hairless skin, passing its life in the waters, and
never voluntarily leaving it for the dry land.

The Cetaceous, or Whale, marine, form his first
section, and are immediately followed by the Cartilaginous fishes, called *Squali* (*Squalo*) by Aristotle. Of the Ceta-
ceae he says that they breathe, like quadrupeds, by means
of lungs, copulate, bring forth their young alive, and
yet approach in some things to the true fishes, and in
their use of all their internal parts agree with those animals.

The following are the genera enumerated by Ray:

**Balaena (2 species);** *Cete* (1); *Orca* (2, but one not clearly defined); *Albus; Monoceros; Delphinus: Phocaen.*

and divides the *Cetacei generalis Pisces, seu Baleae,* into
two great groups—the toothed and toothless; the latter
having horny lamine in the upper jaw.

The Toothed Whales are subdivided into those which
have teeth in both jaws and those which have teeth in
the lower jaw only; and there are further subdivisions de-
pendent on the absence or presence of the back-fin and
the shape of the teeth.

The Toothless or Whalebone Whales are subdivided also
with reference to the absence or presence of the back-fin,
the presence of blow-holes, the employment of nostrils in
respiration, the presence of plats on the belly, and the
width of the lower jaw.

Linnaeus, in his last edition of the *Systema Naturae* (1766), defines the *Fisca* or props of his *Mammalia* to be
four-footed animals with the exception of the cetaceans
which are merely aquatic, in *quibus pedes posteriores in caudae
pinnam comeder;* in other words, in which the posterior
limbs are manacled or conjoined, so as to form a tail-fin.

The seven orders of *Mammalia* in this subdivision are
*Mutica.* The seventh and last order, *Cete,* is the only one
belonging to the section *Mutica.*

The following is the Linnaean definition of the last-named
order:

*Pectoral fins in lieu of feet, and feet conjoined into a
horizontal flattened fin in lieu of a tail. No claws, Teeth
cartilaginous. Nose often a frontal pipe. Food, mol-
luks, fishes.*

*Localia, Ocean.*

Linnaeus then declares that he has separated these cata-
ceans from the fishes, and associated them with the mam-
imals, on account of their warm bicipital heart, their lungs,
their moveable eyelids, their hollow ears, *penem intractum*
transmitting them with proper reasons, &c. and the numerous
express words, *ex lege nature juris moritoe.*

Here then we find the decisive step taken, with the
unfinishing firmness of a master mind, relying upon the
philosophical principles that demanded the separation, and
the consequence of placing them in a class apart, the fish
which he knew to be a mammiferous animal. Some
parts of his definition—much of it—may be open to
criticism, as where he designates the teeth as caralliginous,
a term probably used to comprehend both the horny
toothed whales and the true teeth of the other cetaceans;
but the broad line of distinction is im-

satisfactory, and will ever remain.

The order *Cete* is thus summarily defined by its great
founder: —
Spinescules upon the head. Pectoral fins and horizontal caudal fin without claws.

Genera: Monodon, Balaena, Physeter, Delphinus.

This, the last order of the Linnæan Mammalia, is immediately preceded by the Beluga.

The Cétacés form Cuvier's ninth and last order of Mammalia, the Ruminants (Percaea, Linn.) being the eighth.

Cuvier, as we have seen, divided the orders of the mammals which he defined as mammiferous animals, into those with teeth and those without. Without further consideration, we see at once that the cetaceans are mammals without teeth, and without posterior feet. Their trunk, he states, continues itself with a thick tail, which a cartilaginous horizontal fin terminates, and their head is joined to the trunk by a neck.

The ears, of which, he observes, some part is perceptible, and composed of cervical vertebrae, which are very delicate, and in part joined or soldered together. Their anterior extremities have the first bones shortened and the succeeding bones flattened and enveloped in skin: this gives nearly entirely the external form of the fishes, except that these last have the tail-fin vertical. The cetaceans therefore remain constantly in the water; but as they aspire by means of lungs, they are obliged to come frequently to the surface for which their broad flat ears open externally, although with very small apertures: their viviparous generation, the texts by means of which they suckle their young, and all the details of their anatomy, sufficiently distinguish them, Cuvier observes, from the fishes.

The same great zoologist remarks that their brain is large and its hemispheres well developed; the petrous bone, or that portion of the cranium which contains the internal ear, is separated from the rest of the head, and only by the bony membranes. There is no external ear, nor are there any hairs upon their bodies. The form of their tail obliges them to move it from above downwards for their progressive motion, and aids them greatly in maintaining their position in the water.

For those genera, which, up to Cuvier's time, naturalists had reckoned among the Cétacés, he adds those which had formerly been confounded with the Walruses, and which form their first family, viz.:

The Herbivorous Cetacea.

The teeth of these have a flat crown, which, Cuvier remarks, determines their mode of life, loading them often to leave the water to creep and feed on the bank; these have two teeth on the breast, and hairy moustaches; two circumstances, he observes, which, when they have been seen from a distance with their heads raised vertically out of the water, have given them some resemblance to women or men, and have probably given origin to the stories of some travellers who pretend that they have seen Trolls. They have no front teeth; the battle-axes or boar's tusks open upwards, they are only pierced in the skin at the end of the muzzle. Their stomach is divided into four pouches, two of which are lateral; and they have a great caecum.

Cuvier divides the Herbivorous Cetacea into—
1st, the Lamantins, or rather Manatees (Manatus, Cuv.);
2nd, the Dugonges, Lacep. (Halicore, Ill.);
3rd, the Stel-eres, Cuv. (Rytiria, Ill.).

Cuvier's second family of this order consists of the 'Ordinary Cetaceans.'

These are distinguished from the preceding by the singular apparatus which has procured for them the French name of Stenflous, or Blowers. As they take, together with their prey, very large volumes of water into their vast gaping mouth, there was a necessity of some outlet to get rid of it; it passes across the nostrils by means of a particular disposition of the velum palati, and is collected in a sac placed at the external orifice of the cavity of the nose, whence it is driven out with force by the compression of powerful muscles by a narrow aperture pierced at the top of the head. Thus it is, adds Cuvier, that they produce those jets d'eau which cause them to be seen afar by voyagers.

Mr. Bennett, it is true, in a paper read some time since before the Zoological Society of London, on the habits of the Cachalot, denies that it ejects water from the blow-hole, and asserts that the spouting consists only of the accumulated mucus and condensed vapour of exhalation; but Mr. Bell well observes, in answer to this, that we have not only the positive attestation of M. Lesson, P. C., No. 1714, who declares that he has seen them spout water when he was within a few yards of them, but the admission of Mr. Bennett himself, who says that the blow-holes serve to carry off the water received into the mouth when feeding.

Mr. Bell remarks, in conclusion, that the discrepancy may probably have arisen from the fact that some species spout more than others.

But to return to Cuvier. He further observes that their nostrils, incessantly traversed by floods of salt water, could never, by ordinary means, become malleable animals, and that the special perception of odours. The whales therefore are without those projecting laminæ which are to be found in other animals; the olfactory nerve is wanting in many, and if they have it, it is not of much use to them, for they are very much oblitered. Their larynx, of pyramidal form, penetrates into the back nostrils for the reception of the air and for the purpose of conducting it to the lungs, without any necessity on the part of the animal to lift its head and mouth out of the water; there are no projecting laminæ in their glottis, and their voice must be reduced to simple bellowings. They have no vestige of hair, but their body is covered with a smooth skin, under which lies the thick blubber abounding in oil, and the principal organ of their life, a sac into which the water and the anus, and they are unable to seize with any of their fins. Their stomach has five, and, sometimes, as many as seven distinct pouches; in lieu of a single spleen they have two small and globular organs; their teeth have two cusps, and similar to each other; they do not masticate their food, but swallow it rapidly. Two small bones suspended in the flesh near the anus are the only vestiges of posterior extremities. Many have on the back a vertical fin, much as in the sea-horses, but not sustained by bone. Their flattened eyes have a thick and solid sclerotic; their tongue has only smooth and soft integuments.

Cuvier divides this group into two small tribes: 1. Those whose head bears the ordinary proportion to the body; and 2. Those which have the head disproportionately great.

1st Tribe.

Genera: 1. Delphinus, Linn.: with the subgenus Delphinos, Cuv.; Phocaenides, Cuv.; Delphinopterus, Laeçp.; and Hyperoodon, Lacep.

2nd Tribe.

These cetaceans have the head so large, that it is either a third or one-half of the length of the body; but neither the cranium nor the brain participates in this disproportion, which is entirely due to an enormous development of the bones of the face.

Genera: 1. Physeter, Linn. (the true Cachalots); with the subgenus Physeter, Lacep. (Cachalots with a dorsal fin).
2. Balaena, Linn. (Whalebone Whales): with the subgenus containing the Balanopterus of Lacépède, viz. the Balanopterus with a smooth belly; and the Balanopteris; the first with a plaited belly, commonly termed Balaenas. (Régne Animal.)

M. Lesson divdes the Mammiferous animals into three sections: 1. Those with unguiculated toes (Unguiculata of authors). 2. Those with ungualated toes (Ungulata of authors). 3. Those with unguiculated toes (Ungulata of authors). Of the third section there is only one tribe, the eighth and last in M. Lesson's system, thus defined:

Teeth variable in number, often replaced by horned laminae, body organized for living in the water; two teats.

Cetacea. These are separated into two divisions:

1. The Herbivorous Cetaceans.
2. The Cetaceans properly so called.

These M. Lesson subdivides into two groups: 1st. Those with a small head; 2nd. Those with a large head.

Mr. Swainson takes the 'Cetacea' as the third order of Mammalia, placing it between the Fishes, the last family of which is formed by the Phocidea, or Seals, and the Ungulata, the 1st tribe of which consists of the 'Pachydermes.'

The Cetaceans are thus defined by Mr. Swainson:

Body pisciform; pectoral fins two; caudal fin one, horizontal; ears with a very small external opening.

Vol. XXVII. — 2 N

Grinding-teeth with flat crowns; whiskers hairy; nostrils placed at the muzzle in the skin; body very large; mammae two on the breast.

Family 2. Ceti.

Teeth conical or wanting; nostrils assuming the form of spiracles; skin smooth, shining, and destitute of hairs in every part; mammae placed near the vent.

Small-headed Cetacea: head moderate; canine teeth, or none; carotid. Genus: Cetodon, B.; Phocaena, C.; Delphinus, Linn.; Delphinapterus, Lacép.; and Uranodon, Ill.

Head disproportionally large: of these the two first genera are furnished with teeth in the lower jaw, which are wanting in the two last groups.

Genera: Physeter, Lacép.; Catodon, Lacép.; Balæna, Linn.; Balanoptera, Lacép. (Classification of Quadrupeds.)

M. F. Cuvier thus arranges the order Cetacea:—

Tribe 1. Phytophaga.

Char.—Teeth of different kinds; molaæ with flattened crowns, corresponding to the vegetable nature of their food. Lips provided with tapering bristles. External nostrils always two, situated at the extremity or upper part of the rostrum, which is obtuse.

Genera: Manatus, Cuv.; Halicore, Cuv.; Rytina, Ill.

Tribe 2. Zoophaga.

Char.—Teeth of one kind or wanting, not adapted for mastication. Mammae two, pudendal. External nostrils double or single, situated on the top of the head.

A. With the teeth modified as incisors.

Family Delphinidae.

Char.—Teeth in both jaws, all of simple structure, and generally, conical form. No sacæm. Genus: Delphinorhynchus; Delphinus; Iniæ; Phocaena, Lacép.; Delphinapterus, Lacép.

M. F. Cuvier is of opinion that the following genera seem to form the types of as many distinct families of Zoophagous Cetaceans.

Genera: Monodon; Hyperodon; Platanista.

B. With the head of immoderate size, equalling one-third the length of the body.

Family 1. Catodontidae.

Char.—Teeth numerous, conical, but developed only in the lower jaw. External nostrils or blow-holes confluent; no sacæm.

Genera: Catodon; Physeter.

Family 2. Balaenidae.

Char.—No teeth; their place supplied by the plates of baleen or whalebone, attached to the upper jaw. Blow-holes distinct; a sacæm.

Genera: Balaenoptera; Balæna. (Histoire Naturelle des Citadels, &c.)

Mr. J. E. Gray makes the whales (Ceti) the third order of Mammalia, stating that they are peculiar for their fish-shaped, nearly bald body; that their hinder limbs are united, forming an horizontal tail; and that they have simply conical rootless teeth or whalebone in the jaws.

The family of the whales (Balaenidae), he observes, have a total of the least one third the length of the body, as the tribe of whales (Balæna), which have whalebones in the jaws, and the Catodonts or Physeterina, which have simple conical teeth, as the Spermaceti Whale (Catodon), and Cachalot (Physeter).

The family of porpoises (Delphinidae), which have a moderate or small head and an elongated or smooth body, as the Dolphins (Delphinus), which have conical jaws and teeth, the Porpoises (Phocaena), which have a shorter head and compressed, long, thin jaws, which only have a few teeth,—all these, Mr. Gray observes, have front limbs, while the Susuk (Platanista) has triangular truncated limbs, an elongated beak with compressed teeth, and the bones of the skull bent over the forehead, so as to form an arched cavity.

In the other families, Mr. Gray remarks, the skin is more or less porous, and the lips always furnished with rigid whiskers; the teeth are flat-topped. The Manatees (Manatidae) have eight grinders in each jaw, and the tail rounded at the end. The Dugongs (Halicoridae) have only three or five grinders in each jaw, and the end of the tail truncated or two lobes.

* Ceti.

Family 1. Balaenidae.

Family 2. Delphinidæ.

Genera: Delphinus, Delphinorhynchus, Phocaena, Delphinapterus, Heterodon, Manodon, Hyperodon, Platanista.

** Sirenia.

Family 3. Manatidae.

Genus Manatus.

Family 4. Halicoride.

Genus Halicore.

Family 5. Rytinidae.

Genus Rytina. (Synopsis Brit. Mus.)

Organization.

Phytophagous Cetaceans.

Skeleton.

Lamantin or Manatee.—The nasal bones in the skull of the Manatee are very small, almond-shaped, separated from each other, and let in on each side in a notch of the frontal bone. The result is, that while the nostrils are very large, there is an opening in the bony nostrils. The rest of the bones of the nose are nevertheless replaced by cartilages, so that in the living animal the opening of the nostrils is, as ordinarily, at the end of the muzzle. The intermaxillary bones consist of a single bone in the adult, not at any period reabsorbed except during the first days of embryonic existence; they are notwithstanding very much extended longitudinally, and they re-ascend along the edge of the nostrils to above the region of the eye. The orbits are very much advanced, and very projecting below.

The orbital hole is pierced in the re-entering frame of the orbit with the anterior part of the maxillary bone, so that it is not perceptible when the cranium is seen in profile. This projection of the orbit causes the distance between the lower external border of the sphenoid portion of the intermaxillary bone and the teeth to be greater than the width of the palate. The frontal bones, whose anterior branches are much separated, in order that they may embrace the aperture of the nostrils and form the walls of the orbits, each being off an oblique postorbital apophysis. The cheek-bone extends throughout the lower half of the orbit on the orbital apophysis of the maxillary bone, and thus borders the whole of the orbit anteriorly; it gives off a postorbital intermaxillary apophysis. A bony laminal bone is set in at the posterior angle between the frontal, the jugal, and the maxillary, which intervenes at this point between the lacrimal and the jugal bones. A little lower down, in a depression, is pierced the large suborbital bone, which is thus joined to the edge of the orbit, and cannot give place to any canal. The dental part of the maxillary is more inward than the orbit, so that the interior part of the wall of this cavity is formed by a flat advancement of that bone. The zygomatic apophysis of the temporal bone is thicker than in any other animal, but the rest of the bone is moderate; it contributes to form the sides of the occipital crest, and leaves above, between it and the superior and lateral occipital, a space which permits the petrous bone to be turned, the base of the skull being thus placed in a plane running in a nearly parallel direction, and do not unite in a single line, as in the greater part of the Carnivora. In the adult there is only a single unequal parietal bone, which enters largely into the temple; but in the fetus there are a series of small bones, separated by a connective tissue, which four bones however speedily unite, not only with each other, but, what is singular, with the upper occipital, even before the other parts of the occipital are united. The place of the occipital is thus carried from before backwards, and from above downwards, and the occipital crest makes an obtuse angle; there is no vestige of a mastoid apophysis. Below, the intermaxillaries form the point of the muzzle, occupying nearly the fourth of the palate, and surrounding a large incisive hole, which is single, because they have no internal apophysis. Very young Manates have a small tooth in each of their

* Balaenoptera

† Too near to Physeter.

Digitized by Google
intermaxillaries, thus completing, Cuvier observes, their analogy with the *Dugong*. He observed this in the fetus, but he remarks that the tooth disappears at a very early period. The jaws commence a little behind the sub- 

orbial hole, which, from the disposition of the orbits, is found nearly at their level. The palatine bones advance in row, and oblique pro- 

ceed to unite with the lower boundary of the palate, and contribute to the formation of two large pterygoid wings, whose body is in other respects almost entirely sphenoidal, and does not separate itself from the body of the posterior sphenoid even in the fetus. The temporal also of the sphenoid remain distinct much longer.

The palatine bone shows itself in the temple by a narrow tongue-shaped process, between the maxillary on one side and the anterior sphenoid and the frontal on the other; but its continuity is partially hidden by the dental portion of the maxilla, with which it is continued backward to the wing of the sphenoid, which it touches without articulation. The anterior sphenoid also only shows itself in the temple by a narrow tongue-shaped process, but much shorter than that of the palatine. It does not reach the 

posterior bone, and the orbital wing of the sphenoid touches the frontal. The body of the basi-sphenoid and of the two sphenoids are conjoined with each other and with the cribriform plate of the ethmoidal bone, considerably before the basi-sphenoid unites with the ethmoidal ossicles. The area of the section of the cranium is nearly half of that of the face; it is singularly high, especially before, in proportion to its length. The frontal bones are there nearly vertical; the cribriform plates are found below the anterior surface; they are small, not much pierced with holes, and nearly sunk. The crista galli is prolonged more backwards than they are. There is no sella; the whole base is united; the median fossa hardly depressed. The analogous hole of the sphen-palatine is large, and entirely in the palatine bone. The palate, in particular, is prolonged backward to the form of a canal; the sphen-orbital, which comprises also the ro-

tundum, is rather large and of oval form; the foramen ovale is a notch of the border of the posterior sphenoid, completed by the tympanic bone; the conoidoidean is very small, and it is united at the notch of the lateral orbital canal. The articulation of the lower jaw is formed by nearly flat surfaces, as in all the *Herbivora*. The ascen-
ding ramus is very wide, and its posterior angle rounded. The coronoide apophysis is directed forwards, and truncated nearly into a hatchet-shape. The region of the symphysis is thick and elongated anteriorly. The whole portion that supports the gum is perforated with small holes. The holes for the exit of the lower maxillary are very large. The lateral and dental portions of the lower jaw are very large and rounded.

Cuvier then points out the modifications necessary to convert the cranium of an ordinary quadruped, a ruminant for example, into that of a manatee, and gives an elaborate description of the changes that have taken place in the face of the latter. The limits do not permit us to follow, but which will be found in the *Ossae mena Fossiles*. This is the bone which was formerly considered a specific against diseases of the urinary passages and against hemorrhages. It will be necessary here to observe that Camper denied the existence of the semicircular canals in the manatee, as well as in the whales generally, but with very small ground for the denial, according to Cuvier, who states that they are only excessively delicate.

The shoulder-blade is nearly semi-elliptical; its lower line being almost straight and answering to the great axis of the ellipse: the spine occupies only the anterior half of the bone. Its greatest projection is near its root; it is prolonged forwards into a pointed acron which ascends a little obliquely, and which has the air of terminating by an articular facet. There are no clavicles. A strong blunt tubercle occupies the place of the coracoid process. The humeral surface is a little higher than it is wide, and very concave. The upper part of the humerus is also very convex; its external tuberosity is very projecting. The bicipital groove is not deep, but there remains a deep canal between the internal tuberosity and the articular head; the deltoidean crest is but little marked. The lower head is a rather oblique simple pulley, ascending at the internal edge. Its width is not greater than its antero-posterior diameter. The internal condyle projects much more than the other backwards. The ulna and radius, which are rather short in proportion to their stoutess, and still more so with reference to the size of the animal, are joined together by their two extremities. Their upper articulation corresponds to the pulley of the humerus; the head of the radius is wider than it is high, and, even when not conjoined, is incapable of executing rotation; in which circumstance the manatee differs still more widely from the seals, in approximate itself to the *Herbivora*. The radius has, below, at its external surface, two pointed crests. There are only six carpal bones; the pisiform bone is wanting, and the trapezium and trapezoid are united into a single bone, which is articulated at once with the metacarpal bone of the thumb and of the fore-finger. The analogue of the os magnum responds to those of the fore and middle fingers. The unciniform bone responds to the middle, ring, and little fingers, which last articulates itself at the same time with the cuneiform bone of the first row.

Each of these bones has also in the manatee its particular character. The pisiform bone, Cuvier observes, is also wanting in the *Dolphins* and is very small in the *Seals* and *Bloats*, whilst it is very long in the animals which make much use of their fore-feet for seizing or progression. The metacarpal bones are flat above, and carinated below; that of the thumb, which has no phalanges to support, terminates in a point; the others are enlarged at their lower extremity. That of the little finger is longer and most enlarged of all. The ring finger, on the contrary, is that which has the longest phalanges, but those of the little finger are flatter and wider. All the articular surfaces of the phalanges are rather full, and must possess but little mobility.

The shoulder-blade is nearly semi-elliptical; its lower line being almost straight and answering to the great axis of the ellipse: the spine occupies only the anterior half of the bone. Its greatest projection is near its root; it is prolonged forwards into a pointed acron which ascends a little obliquely, and which has the air of terminating by an articular facet. There are no clavicles. A strong blunt tubercle occupies the place of the coracoid process. The humeral surface is a little higher than it is wide, and very concave. The upper part of the humerus is also very convex; its external tuberosity is very projecting. The bicipital groove is not deep, but there remains a deep canal between the internal tuberosity and the articular head; the deltoidean crest is but little marked. The lower head is a rather oblique simple pulley, ascending at the internal edge. Its width is not greater than its antero-posterior diameter. The internal condyle projects much more than the other backwards. The ulna and radius, which are rather short in proportion to their stoutess, and still more so with reference to the size of the animal, are joined together by their two extremities. Their upper articulation corresponds to the pulley of the humerus; the head of the radius is wider than it is high, and, even when not conjoined, is incapable of executing rotation; in which circumstance the manatee differs still more widely from the seals, in approximate itself to the *Herbivora*. The radius has, below, at its external surface, two pointed crests. There are only six carpal bones; the pisiform bone is wanting, and the trapezium and trapezoid are united into a single bone, which is articulated at once with the metacarpal bone of the thumb and of the fore-finger. The analogue of the os magnum responds to those of the fore and middle fingers. The unciniform bone responds to the middle, ring, and little fingers, which last articulates itself at the same time with the cuneiform bone of the first row.

Each of these bones has also in the manatee its particular character. The pisiform bone, Cuvier observes, is also wanting in the *Dolphins* and is very small in the *Seals* and *Bloats*, whilst it is very long in the animals which make much use of their fore-feet for seizing or progression. The metacarpal bones are flat above, and carinated below; that of the thumb, which has no phalanges to support, terminates in a point; the others are enlarged at their lower extremity. That of the little finger is longer and most enlarged of all. The ring finger, on the contrary, is that which has the longest phalanges, but those of the little finger are flatter and wider. All the articular surfaces of the phalanges are rather full, and must possess but little mobility.
vertebrae of the tail are very large, especially in the first, but the spinous processes are inconsiderable, which accords, Cuvier remarks, with the depressed form of the tail-fin to prove that the manatee swims by a vertical movement of the tail. The ribs are similarly stout and thick; their two edges are rounded, and they are as convex internally as externally. Cuvier states that he knows of no other animal that has ribs of this form. The two first pairs of these ribs only unite themselves with the sternum by means of cartilages; the following others and between the same vertebra, to the transverse apophysis of which they are articulated. The ribs are not nearly so stout as in the Manatee, but, notwithstanding, the first are still very thick, and have their edges blunt. After the eighteenth dorsal vertebra, the ribs degenerate into the same twine whose spinous apophyses diminish progressively. In the lumbar vertebrae the transverse apophyses are very long; afterwards they diminish by degrees on the sides of the tail, and again become rather longer at its extremity, apparently for the support of the tail-fin. It would seem that the three first only belong to the loins. The fourth has towards its extremity a facet, which is probably destined for the attachment of the pelvic bones, which last and are directed upwards, its being a large oval, as in the Manatee of Senegal. The whole skull, and particularly the frontal bones, are for the same reason much shorter in proportion than in the Manatee. The branches of the frontal bone which form the upper part of the orbit are more delicate and more rugose. The maxillary portion which serves as a floor for the orbit is narrower; the jugal bone, in turning to form the anterior and inferior edge of the orbit, is more compressed and directed more downwards. There is also a lachrymal bone in the anterior angle, more considerable than in the Manatee, but equally without any hole. The zygomatic apophyses of the temporal bone is more delicate and more compressed. The connections of the bones of the cranium are the same, but at the inferior surface the basilar bone is united with the lateral capitula, rather than with the posterior sphenoid.

The enormous development of the intermaxillary bones of the Dugong carries up the aperture of the bony nostrils much higher than in the Manatee, and it is situated at the superior part of the head in the thirtieth of its length and directed upwards, its form being a large oval, as in the Manatee of Senegal. The whole skull, and particularly the frontal bones, are for the same reason much shorter in proportion than in the Manatee. The branches of the frontal bone which form the upper part of the orbit are more delicate and more rugose. The maxillary portion which serves as a floor for the orbit is narrower; the jugal bone, in turning to form the anterior and inferior edge of the orbit, is more compressed and directed more downwards. There is also a lachrymal bone in the anterior angle, more considerable than in the Manatee, but equally without any hole. The zygomatic processes of the temporal bone is more delicate and more compressed. The connections of the bones of the cranium are the same, but at the inferior surface the basilar bone is united with the lateral capitula, rather than with the posterior sphenoid.

A very great solution of continuity is seen in the bottom of the orbit and of the temple, and establishes in the skeleton an extensive communication between these two fossae, and that of the nostrils; it is intercepted between the maxillary, the frontal, the anterior sphenoid, and the palatine bones. The continuity of the temporal portion of the palate with the rest of the bone is not here concealed, as in the Manatee by a production of the basilar bone. The occiput is narrower and its crest less marked than in the Manatee; the frame of the tympanum is also narrower and more delicate, but the bone of the ear is disposed in the same way, and is let in between the same bones. There also remains in the skull a large empty space between that bone, the basilar, and the anterior sphenoid. Within the cranium there is no bony tentorium; the cribiform fossa is reduced to two simple depressions very much separated from each other, and which terminate anteriorly by two or three small holes. There is no sella Turcica. The optic aperture is a long narrow canal. The lower jaw is of a height corresponding with the curvature and length of the intermaxillary bones. This part shows in the adult the remains of three or four alveoli on each side.

The atlas is very similar to that of the Manatee; the axis the same. The five other cervical vertebrae are very delicate, but not conjoined. There are eighteen dorsal vertebrae, the spinous apophyses of which are arranged nearly in a straight line. Counting from the ninth, the ribs do not attach themselves to the same vertebra, to the transverse apophysis of which they are articulated. The ribs are not nearly so stout as in the Manatee, but, notwithstanding, the first are still very thick, and have their edges blunt. After the eighteenth dorsal vertebra, the ribs degenerate into the same twine whose spinous apophyses diminish progressively. In the lumbar vertebrae the transverse apophyses are very long; afterwards they diminish by degrees on the sides of the tail, and again become rather longer at its extremity, apparently for the support of the tail-fin. It would seem that the three first only belong to the loins. The fourth has towards its extremity a facet, which is probably destined for the attachment of the pelvic bones, which last and are directed upwards, its being a large oval, as in the Manatee of Senegal. The whole skull, and particularly the frontal bones, are for the same reason much shorter in proportion than in the Manatee. The branches of the frontal bone which form the upper part of the orbit are more delicate and more rugose. The maxillary portion which serves as a floor for the orbit is narrower; the jugal bone, in turning to form the anterior and inferior edge of the orbit, is more compressed and directed more downwards. There is also a lachrymal bone in the anterior angle, more considerable than in the Manatee, but equally without any hole. The zygomatic processes of the temporal bone is more delicate and more compressed. The connections of the bones of the cranium are the same, but at the inferior surface the basilar bone is united with the lateral capitula, rather than with the posterior sphenoid.
With regard to the rudimental pelvic bones in the Dugong, he remarks that in the true Cetacea the parts analogous to the ischia are alone present, and that they serve a similar purpose to that in the Dugong.

**Zoophagous Cetaceans.**

Dolphins.

The skull in the Dolphins is very much elevated, very short, and very convex behind. The occipital crest surrounds the top of the head, and descends on each side on the middle of the temporal bones, which are directed much more backward than the frontal. The mandibular notch is placed behind the posterior, the frontal, and the internal pterygoid apophysis; but the great peculiariy is the form of the back nostrils. The maxillaries being prolonged into a flattened muzzel, and the teeth terminating in front, the base of the floor nor on the anterior or lateral walls of that cavity, but at its ceiling, as is also the jugal bone: it completes the inner border of this ceiling. From the entire posterior contour of the lower surface or palatine of these bones, the maxillary bones rise a sort of quadrangular pyramid, whose base is traversed vertically by the nostrils, and in which the rest of the space is hollow, or contain'd between two laminæ open behind. These form a sort of double walls which surround the posterior aperture of the nostrils. They are composed of the palatines and the pterygoid internal apophyses. Each palate is folded back on itself in an irregular ring, to form the base of this double wall, and the ceiling is completed by the maxillary, to which it is articulated. The internal pterygoid apophysis is only return'd in the form of S. One of its curvatures articulates itself externally to the palate to prolong the lower and external wall; the other unites to the other arch of the palate, and afterwards continues on the anterior sphenoid to articulate itself to the vomer, and thus complete the internal part of this entourage of the back nostril; whence it results that the entire border of the back nostril, except the vomer, belongs, as in the Ant-eaters, to the internal pterygoid apophysis. The great sinus intercepted between the end of the orbit and sphenoida in the dolphin: this internal pterygoid always remains distinct. The posterior sphenoid is conjointed with the basilar much sooner than to the anterior sphenoid: Cuvier even found it conjointed in some fætuses before any of the other bones. This nearly absolute conjointment of the bases has, Cuvier observes, much changed the direction of the holes. In place of the incising hole there is a long canal which proceeds between the two maxillaries and the two intermaxillaries, from the end of the muzzle to the nostrils, near which it bifurcates. The suborbital hole is to be sought in the ceiling of the orbit, where it represents a cavity open below, from which proceed in different directions canals which go to open on the superior surface of the maxillaries and intermaxillaries, not below, but above and opposite to the orbit. Cuvier could find neither lachrymal bone nor hole. In a hollow in front of orbit, between the maxillary, the vomer, and a point of palatine bone, is a small hole, which ascends in the and represents the spheno-palatine. To remove the pterygo-palatine, Cuvier could only perceive on the junction of the palatine to the maxillary, which enters the sinus placed on posterior nostrils. The optic hole is most anterior sphenoid, as ordinarily. The union between the two sphenoids also perforates the round hole. There is an oval hole and more internally in the same vessel. An aperture between the occipital, the basilar, and the
passage to the nerves of the ear to go to the petrous bone. In front of it, and very near, is the carotid bone hole. In the basioccipital bone, and in a notch of the borders of this vault of the ear, is the condyloid hole, which is very small. It is the posterior border of this vault which occupies the place of the mastoid apophysis.

Internally the cerebral cavity is very remarkable, inasmuch as its height surpasses its length. The floor is very concave and the base is but slightly marked. The cerebellar fossae are the most hollowed; there is often a very projecting bony tentorium in its middle; the falx is always bony backward, but it has no crest, and some small holes are scarcely perceptible in the cribiform plate. The petrosal and tympanic bones are not joined to the cranium by any suture, and are not even enclosed, but are sur-

The skull of Porpoises.

The common Dolphin the seven cervical vertebrae are united in a single body, and so are they in the Porpoises; but this is not universally the case, for in the Dolphin of the Ganges, for instance, the cervical vertebrae are as distinct as in any quadruped. But where they are ankylosed, as in the Pelagic or Deep-sea species of Dipnoi, the atlas is entirely developed, and the axis is sufficiently strong; transverse, conic apophyses. The head of the axis is very delicate; but its spinous apophysis, ankylosed to the atlas, is also well marked. The four suc-

The skull of the Narwhal resembles that of the dolphins and especially the head of the Beluga in structure: but instead of the numerous teeth ranged along the maxillaries and mandibles, generally three, five, or seven on each side, directed forwards and implanted in an alveolus common to the maxillary and intermaxillary bones. lower jaw has not the symphysis longer than in the ordinary species of the dolphins.

The seven cervical vertebrae are all ankylosed together; there are thirty-eight other vertebrae, nine of which carry the ribs. At the twenty-second the V-shaped bones which characterize the first caudal commences, so that seventeen caudal vertebrae may be counted. The six of these V-shaped bones; and the superior spinous apophyses cease on the ninth caudal. The five first ribs only are articulated to the sternum, and there are only four false ribs on each side. The sternum is composed of three bones: the first square, notched in front and behind; the second square also, and notched in front; the third oblong and notched behind.

The shoulder-blade has the spiral border more extended in proportion and more rectilinear than in the dolphins, the anterior angles more pointed, the acromion column is in part also oblique downwards, and the coracoid process a little in the opposite direction. The bones of the arm and fore-arms are a little less shortened than in the dolphins. (Oseous Passilies.)

Cachalot.

The skull of a Cachalot bears a nearer resemblance to that of the Dolphins than to that of any other cetaceans. The immense muzzle, notwithstanding its prodigious extent, is, like that of the dolphin, formed by the maxillaries on the sides, the nasals posteriorly, and the vomer on that line. The intermaxillaries reach beyond the other bones to form the anterior point; they ascend on the two sides of the nostrils and the nasal bones, and raise themselves to form that species of wall which elevates itself particularly and circularly on the back of the head, but that of the right side is carried higher than that of the left; the vomer shows itself between them in considerable width, especially at the upper part; it is hollowed into a semicircular channel throughout its depth. The nostrils are pierced at the foot of this sort of wall at the root of the vomer, and between the raised and ascending parts of the two intermaxillaries. Their direction is oblique from below upwards, and from behind forwards. They are excessively uneven, and that on the right is a fourth of the size of that on the left. The nasal bones are also very unequal: both ascend between the intermaxillaries against the foot of the semicircular wall which is raised upon the enunium, but they only rise to the level of the left intermaxillary. The right nasal bone is not only larger than the other, but it also descends lower between the two nostrils, articulating itself upon the root of the vomer, and giving to that part an irregular crest which reposes a little obliquely on the left nostril, which, as before observed, is the left nostril.

The direction of the vomer and amplitude of the left nostril indicate a direction of the membranous canal of the nostrils and the whole spouting apparatus towards the same side, and explain, Cuvier observes, the fact observed by astronomers, namely, that the cachalot throw their spoutings towards the left side.

The maxillaries do not join each other in front of the semicircular wall; and leave exposed between them an irregular and considerable part of the frontal bone, which goes behind them, and, directing itself laterally, proceeds to form, as in the dolphins, the principal part of the ceiling of the orbit; the maxillary makes its anterior angle, in front of which the border of the maxillary has a deep notch, and at its upper surface, opposite to the notch, is the post-orbital fossa which occupies the place of the suborbital, but which, Cuvier remarks, should here be called supra-orbital. The posterior angle of the orbit is occupied by the point of the zygomatic apophysis of the temporal bone, but it does not join the post-orbital sinus of the frontal bone, so that the edge of the orbit is open at this point. The lower part of the orbit is formed by a stout and cylindrical jugal bone, whose anterior part dilates itself into an oval plate with a point which projects beyond the orbit in the temple; the temporal fossa is very deep, rounded, but not distinguishable by a crest from the rest of the occiput: a little of the parietal bone is perceptible between the temporal and the frontal bones. The squamous portion of the temporal bone is in the shape of a stout and short cone; proceeding to the orbit, it forms the arch, as in the dolphins. The occipital bone is vertical and forms the whole posterior surface of the circular wall which surrounds the skull behind.

The skull and teeth of Narwhal, seen from below. (Owen.)

Hyperodones.

The skull in this genus differs almost entirely in form from those belonging to the dolphins. From the maxillaries, which are pointed in front and widened towards the base of the muzzle, rises on each of their lateral borders a large vertical crest, rounded above, descending obliquely forwards and more rapidly backwards, where it falls again nearly above the postorbital apophysis. Still more backwards, the maxillary bone, continuing to cover the frontal bone, ascends vertically with it and with the occipital, in front on the back part of the head a transverse occipital crest, which is very elevated and very thick: so that on the skull of the animal there are three of these great crests; the occipital crest behind, and the two maxillary crests on the sides, which are separated from the first by a wide and deep notch. They do not approximate above nor do they form a vault, as in the Dolphin of the Ganges, but simply a sort of lateral walls. The intermaxillaries, placed as ordinarily between the maxillaries, ascend with them to the nostrils, and passing by the side of them, raise themselves above so that they take part in the formation of the posterior crest elevated upon the occiput. The two nasal bones, which, as well as the nostrils, are very unequal, are placed at the anterior surface of this occipital crest, and are raised to its summit. In other respects the connections of the bones are nearly as the same in the dolphins.

The zygomatic apophysis of the temporal bone is thick, without being as long as in the Dolphin of the Ganges; the orbit is as wide as in the ordinary dolphins, and bordered in like manner below by a slender stem given off by the jugal bone. The parietal bones show themselves but very little in the temporal fossa, which is itself not much extended in height. Below, the palate is slightly arched, indicating an approximation to the Baleen. The lateral furrows observable in the common dolphin are absent. The pterygoideans occupy a very great length in the back-nostrils and much diminish the portion which the palatines bones fill in front. The vomer shows itself at two points of the lower surface, between the pterygoideans and the palatines, and between the maxillaries and intermaxillaries. The occiput is higher than it is wide. The
pital hole is nearly at the lower third of its height. The lower border of the occipital bone is divided on each side by a notch into two lobes, the external of which represents the mastoid apophysis.

The lower part of the skull, allowing for the difference of proportion of the parts, much resembles the lower portion of that of the dolphins. The region behind the nostrils is very much shortened in comparison of that which is anterior to them, and of which the enormous muzzle forms the greatest portion. The result of this conformation is that the basiary and posterior sphenoid are very short; that the anterior sphenoid, as in the large-muzzled dolphins, only shows itself below in a notch of the vomer, and appears very little towards the temple between the palate, the pterygoidean, and the temporal arch of the posterior sphenoid; and that the pterygoideans extend on their lateral and posterior part, nearly to the posterior portion of the basiary bone. The jugal bone on its anterior part lines below a great portion of the vault of the orbit, and proceeds to touch, behind, the points of the two sphenoideans. Their anterior border is not double, as in the dolphins. The bone of the ear bears a great resemblance to that of the dolphins, but the tympanic bone is less elongated and less lobated backwards.

Of the cervical vertebrae of the Cachalot, the atlas alone is distinct: the six others are ankylosed into a single mass by the bodies and spinous apophyses; but the number may be made out by the sides, where very delicate laminæ interpose between the holes where the nerves pass out. There are fourteen pairs of ribs and fourteen dorsal vertebrae (perhaps a fifteenth), and thirty-five others—sixty in all. The dorsal have their transverse apophyses turned inwards, and embrace the posterior, which look outwards. The spinous processes are less elevated and wide from before backwards. The two last carry the ribs only on the extremity of the transverse apophysis, and not on a facet of the body. On the succeeding vertebrae the spinous apophyses rise, become oblique, and wider at their summit than at their base. The articulars ascend gradually to their anterior borders, as in the dolphins: the spinous apophyses remain in the same plane, and their summit on the tail, and finally disappear. The spinous apophyses disappear also on the last caudal vertebra. The transverse apophyses are, at first, simple tubercles of the articular apophyses: they do not take the form of dist, which is less than those of the articulars, which form more than the spinous; and, afterwards continue on the lumbar and caudal, but always remaining of moderate length, and not dilating at their extremity. The lower part of the body of the vertebra, counting from the fourth lumbar, is strongly constricted. The notched bones do not commence before the twenty-first after the dorsal vertebrae. They are at first rather long, and more so than the spinous apophyses to which they correspond; but afterwards they are a little shortened. The vertebrae which carry them have their greater articulars divided into two truncate ridges, each at the two extremities, so as to form facets for the V-shaped bones, which always articulate between two vertebrae. The caudal vertebrae still remain very large up to the six or seven last, which diminish rapidly, losing their distinct eminences; thus the greatest portion of the spine is nearly much of a size.

The shoulder-blade is coneae externally, convex on the side of the ribs, and narrower than in the other cetaceans: its spinal border is not two-thirds of its length. The anterior border becomes double below the middle of its height, and gives off from its external ridge a great acromion, more projecting anteriorly than the shoulder-blade is at this point, and enlarged at its extremity. The internal border goes off near the articular head a concoid apophysis, which projects less than the acromion, and terminates in a point. The humerus is very short and stout, and has at its anterior border a crest, terminated towards the lower part by a hook which represents the deltoid crest. The neck is short before the humerus, even to the epiphysis of this last is united. The olearian apophyses project very much, and curve towards the wrist. (Cetacea Pinni.)

Balænidae, or Whalebone Whales.

Rorqual (Balaenoptera).—The skull of the Rorqual is more approximated to that of the dolphins than the skull of the Balæna properly so called. The immense maxillary bones are disposed below, in form of a reversed roof or a keel, to the two sides of which the baleen, or whalebone, is attached. The vomer is situated between these, at the mesial line of the keel. Above, the two intermaxillaries, placed parallelly between the two maxillaries, leave between them a vacant space, which is continued above, rather backwards, with the very large aperture of the nostrils, which is in the form of an elongated oval, and, contrary to the other cetaceans, preserves, as in the whole of the Balæna, a symmetrical form. The nasal bones, which are short, but notched or festooned anteriorly, and not in form of tubercles, form the upper border of the aperture. The maxillary does not cover the frontal bone, except by a narrow apophysis on the sides of the nasal bones. The whole portion of the frontal bone which goes on each side to form the orbit is exposed, but the maxillary only cover the temporal part, and is attached to the sides of the apophysis of the maxillary bone, which shows itself between the frontal and the bones of the nose. The occipital bone advances between them, and covers the middle of the frontal to near the base of the nose; so that at the base of the nose the frontal does not show itself externally. There are two temporal crests projecting greatly forwards, commencing at the sides of the nose, and between which the skull is flat, or even slightly con cave, and descends slowly towards the occipital hole, which is at the extremity of this plane. The occipital crest comes near...
the base of the nasal bones, traversing from one temporal bone to the other. On the middle of this occipital surface is a slight projecting longitudinal ridge. The temporal bone is not dilated at its extremity, as in the dolphin. The frontal on one side touches the maxillary, and on the other the temporal bones, by its ante- and post-orbital apophyses, and forms the roof of the orbit, which is without being doubled above by the maxillary; but, on the other hand, is below, on its anterior portion, that in front of the orbit, and moreover is bordered there anteriorly by the lateral lamina of the maxillary bone, which is, with reference to this, very much narrowed. In them the rostrum is molded to the transverse apophyses which carry the ribs. There are fourteen dorsal vertebrae and as many pairs of ribs, and thirty-one other vertebrae to the end of the tail—fifty-two in all. The second, third, and fourth ribs only have heads, and the rest seem hardly able to bear the vertebra. The others only reach the extremities of the transverse apophyses, which go on lengthening to the lumbar region. They are longer than they are wide, and dilate at the end, as in the Greenland whale. They thus continue to the thirteenth lumbar, and thence to the dorsal. There is a little ridge on the middle of the back, narrower, but always moderately elevated, on the lumbar region, and shortening by degrees on the tail. They vanish on the twelfth last, and the lumbar portion disappears. The faces of the articular apophyses look inwards as far as the eleventh, where they begin to open outwards. They do not rise, and finally form, towards the fourteenth or fifteen, with the spines (which is always marked), the angle of the twelve to the eighteenth. The French skeleton is attached under the ninth lumbar vertebra. At the eleventh the V-shaped bones commence. The first is still formed of two separate bones. They re-divide again near the hind limbs. The posterior part of the lumbar and caudal vertebrae is hardly marked, as slight cartilage. Commencing from the fifteenth vertebra after the dorsal, the body of each is pierced on both sides, above and below, with a large hole for the vessels. These holes do not diminish on the last caudal, though they are much smaller, and each they represent two cylinders set back to back, pierced in their axis.

The single bone of the sternum was square, deeply forked posteriorly, and with a point at its external border. The shoulder-blade of the Cape Roqual is, Cuvier remarks, entirely different from that of the Balaena; it is wider than it is long, semicircular on the spinal side, with a single angular border, and a single prominence (the acromion) towards the lower third, and a tubercle near the articulation, which is the coracoid apophysis. The humerus is still stouter in proportion than that of the Balaena, but the bones of the for-arm are much more elongated. The fin is also much more pointed. There are only four well-marked fingers, which do not equal the number of the following joints—the index two, the middle and ring finger seven each, and the little finger three; all the fingers are terminated by a cartilaginous dilatation.

The bone of the ear in the Balaena is very much different from that of the Roqual. It may be supposed to be a thickened thickness of the tympanic bone, especially on the internal side. The tympanic bone is a little more closed in front, but leaves between it and the petrous bone on the internal side a little more than the parrot. It is not bilobated but semi-oval. The petrous bone is of very irregular form, and very rugged; it gives off two great and stout apophyses, also very rugged, one of which, posterior and external, is a corresponding apophysis of the little superior, articulated to a corresponding portion of the transverse and lateral apophysis, and the other, anterior and inferior, is articulated by squamous suture with the temporal portion, which descends to furnish articulation of the cervical or the last cervical. The ear-bones in all the cetaceans are four in number, as in the Roqual, so that the lower jawbone rises a little to offer its articular convex surface. This disposition, joined to the absence of a coronoid apophysis, is a form to distinguish it from the lower jaw of the Roqual.

In the Roqual of the Cape, Cuvier found the atlas distinct from the axis; this last is anchored by the upper part of its ring which has no spinous apophysis, with the corresponding part of the third cervical. This last and the four others do not unite; they are of some thickness. The transverse apophyses are double in the third first, as in the axis; one, superior, is given off from the annular portion of the vertebrae from the base of the bone. There are a few others do not unite; they are of some thickness. The transverse apophyses are double in the third first, as in the axis; one, superior, is given off from the annular portion of the vertebrae from the base of the bone.
in the quadrupeds, and the malleus is anchylosed to the frame of the tympanum, which, Cuvier observes, is the more singular, inasmuch as it is not deprived of its muscles.

Cuvier remarks that the skull of the Greenland whale differs more from the Balea of the Cape than the skulls of the Rorquals differ from each other. He points out these differences, which extend, although slightly, to the bones of the ear; and expresses his opinion that they are different species.

In the great Cape Balea, according to Cuvier, the atlas, the axis, and the five other cervical vertebrae are united together by their bodies. All their spinous apophyses are anchylosed into a single crest. The atlas and axis unite besides by their upper transverse apophyses, which are wide and strong; their lower transverse apophyses, which are equally long and strong, are anchylosed to each other and to that of the third, which is more slender. The four next cervicals have only delicate transverse apophyses, of which the third, fourth, and fifth are anchylosed together. The last also has only one upper transverse apophysis, but longer, stronger, free, and directed forwards. Cuvier remarks that this division of the apophyses into upper and lower responds to the two branches separated by a canal, which are seen in those of ordinary mammals. The transverse apophyses of the first dorsal are directed also forwards, and are long and a little stronger than at the last cervical; they commence increasing in bulk, and shortening at the fourth dorsal. The succeeding take a more transverse direction, and are enlarged at the end, to the tenth inclusive. Counting from the eleventh, they again begin to elongate to the twentieth; they then diminish insensibly to the thirty-fourth, where they disappear. They are throughout longer than in the Cachalot, and enlarged towards the end, the contrary of which is manifested in that genus. There are fifteen pairs of ribs; the four last pairs and the two first do not reach the body of the vertebra, and are only attached to its transverse apophysis. The first pair is flattened and extremely wide, especially at the sternal extremity. The three last are slender and short. After the fifteen dorsal vertebrae come twenty-seven others. The V-shaped bones commence between the eleventh and twelfth; they are small compared with those of the Cachalot, and disappear after the twenty-sixth. The eleven or twelve last vertebrae have no longer any prominence. The last of all are nearly quadrangular, and are each pierced with two vertical holes. The spinous apophyses form a tolerably uniform series of moderate height, all inclined forward; they begin diminishing on the tail. The anterior articular apophyses are not elevated, neither are they depressed, and preserve the same dimensions. They widen on the tail where they have no articulation to furnish, and the five or six last, nearly equal to the corresponding spinous apophyses, form with them on their vertebra a frilled prominence.

The single bone of the sternum was oblong, widest in front, and carried on each side an articular facet for a rib.

The shoulder-blade is nearly flat; one can scarcely perceive a slight concave curvature; it is nearly fan-shaped, and less wide than high. Its anterior border is simple, and has only a single projecting apophysis, which, from its position, is probably the acromion. Its articular head is much wider in proportion than in the Cachalot. The humerus is stout and short, scarcely twice as long as it is thick. Its tuberosity does not reach beyond the head in front; this last is hemispherical, and nearly parallel to the axis. The lower head is divided into two slightly inclined planes by the ulna and radius compressed; the ulna is the narrowest, especially in its middle. Its upper head is slightly oblique at its axis, and the olecranon ascends a little, instead of recurving into a hook, as in the Cachalot. The radius enlarges below, so as to be twice as wide as its length; above, it is not more than one third. There are four carpal bones in the first row, of which the ulnar bone, which responds to the pisiform, forms a projection externally; there are only three in the second. The metatarsals are in length only double their width. The thumb has two phalanges of the ring-finger three, and the little finger three; and all are terminated by a cartilaginous dilatation. A wide and short fin obliquely rounded is the result. (Osseous Fossilies.)

The pelvis in the Cetaceans is, as we have seen, only rudimentary, but it may be necessary here to give a summary of the modification of the bones and their connection with the skeleton in the different groups.

In the Dugong it consists of two pairs of bones joined two and two, and end to end by a cartilage: to the vertebra this apparatus is attached by a cartilage.

The construction of this part varies in the true Zoophagous Cetaceans. Two small long bones lodged in the flesh, one on each side of the anus, form the pelvic radius or Whalesbone in the Dolphins. In the great Whales, the Mysticete, or Whalebone Whale, for example, at the extremity of each of the bones regarded by comparative anatomists as the second, which is smaller and curved, is articulated. The convexity of this last bone is external, and may be considered a pubis or ischium.
Phytophagous Cetacea.—The teeth (molars) of the Manatees are ridged on the inner side, but the root distinct from the crown: here the resemblance to the pachyderms (Tapir and Hippopotamus, for instance) is very strong. The molars of the Dugongs are elliptical without true lags, and with two slight furrows on the unworn crown, which distinguishes them from the corresponding parts of the Manatees. In the Dugongs the teeth are not so large, nor is the anterior cornua usually developed. The Rynites there are no molars; but there is in lieu of them a horny plate in the middle of each jaw. The tongue is short, and can hardly be endowed with much motion. The form of the os hyoides is simple: ankylosis between the body and posterior cornua is not uncommon, but the latter send no ligament to the thyroid cartilage. The anterior cornua remain generally cartilaginous, and are the medium of union between the body or basal-hyal, and the large and long styloid processes.

Professor Owen remarks, that the position of the larynx is chiefly defended, during the submariu mastication of the vegetable food of the Dugong, by the extreme constriction of the fauces aperture, which resembles that of the Cetacea. No pyramidal larynx traverses it, as in the true Cetacea. Two large parotid glands are situated immediately behind the large ascending ramus of the lower jaw. A thick layer of simple follicular glands is developed above the membrane of the palate, and a glandular stratum is situated between the mucous and muscular coats. The former only is lined with a mucosa, but the latter consists of a serous membrane, and an outer connective tissue plane. The stomach, the esophageal duct, and the large caecum are provided with a mucous lining, similar to that with which the stomach is lined in the Piked and Whalebone Whales. It is lined by a single, embryonal epithelium. Professor Owen states that a similar but more developed glandular structure is present in the oesophagus of the Ray. He then observes, that the stomach of the Dugong presents, as Sir Ernest Hume has justly observed, one of the peculiarities of the whale tribe, the presence of a second stomach, the stomach of the Hippopotamus, and the Beaver: like that of the first, it is divided into distinct compartments; like the second and third, it has pouches superadded to and communicating with it; and, like the third, it is provided with a remarkable, glairy, mucus secreting apparatus near each orifice. These modifications, the Professor remarks, obviously harmonize with the difficult digestibility and low-organized matter of the food of the Dugong. 'Yet,' says he, 'it is a fact that would not have been a priori expected, that in the carnivorous Cetacea the stomach is much more simple, and is larger in proportion to the dimensions of the body, than in the herbivorous species, and presents a closer resemblance to the ruminant stomach; it is divided, for example, into a greater number of receptacles, and has the first cavity, like the ruminants, lined with cuticle, while in the Dugong, on the contrary, the cavity is everywhere covered with a smooth mucus membrane. After a luminous detailed account of the stomach, Professor Owen observes, that 'in the primitive form of the stomach, the whole surface of the wall is covered with a network of small veins and lymphatics. It is interesting, he adds, to find that a corpus collo (the situation and structure of which in the Dugong he describes) is present in the true Cetacea, as the Balaenides, which subsist on animal food of the lowest organized kind. The whole of the alimentary canal and the individual divisions presented by the three specimens having been elaborately detailed, Professor Owen proceeds to point out that the Dugong, with respect to the biliary organs, deviates in a marked degree from the ordinary Cetacea in the presence of a gall bladder and an appendix vermiformis. The last is also seen in the Manatees. Professor Daubenton also found in the Manatees; but the presence of the gall-bladder is not, the Professor observes, constant in the herbivorous Cetacea, for in the Northern Manatee, according to Steller, it is wanting, and its absence seems to be common in the class of animals of the Genus Dugong, which would admit the five fingers united. The secretion of the pancreas was carried by to thirty ducts, each about two lines in diameter, to a very wide common excretory canal, which terminates below, but on the same prominence with the esophageal duct; at a much greater relative distance from the pylorus than in the true Cetacea. In one of the Dugongs dissected by Professor Owen were two small accessory excretory segments in addition to the larger rounded one, but in the other specimens the last alone was present. (Zool. Proc. 1836.)

Zoophagous Cetacea. The teeth of the Dolphins are, generally, simple and conical or compressed. They are present in both jaws; their number varies, and they are not always perfectly fitted. The eyes are large, and the nostrils placed in the upper jaw only. Some of the Cachalots are simple, of a long ovoid recurved shape, and placed in the lower jaw only. The Mysticetes, or Whalebone Whales, are without true teeth; in lieu of which, transverse horn-like plates of baleen, or whalebone, as it is commonly called, grow from the edge of the plates on their internal edges are fringed with loose bear, and among these the small marine animals which form their food are entangled as in the meshes of a net.

The stomachs of the Zoophagous Cetacea are very complicated; these in various species and in different individuals of the same species, has been variously given by different authors. Some have stated the number in the common Dolphin and Porpoise at three, others at four, others at five, others at six. M. F. Cuvier considers it as certain that there are six stomachs, which is in agreement with the manner in which the organ is viewed. Professor Owen was unable to distinguish more than four compartments in the stomach of the Porpoise. In general the spouting whales have no cacum; but a trace of it has been found in the Platanist, and it actually exists in the Piked and Whalebone Whales.

John Hunter pointed out the considerable degree of uniformity present in the liver of this tribe, observing that in shape it resembles that of man, but that it is not so large, that at the base of the liver is not so rounded, not so firm in the texture. The right lobe is the largest and thickest. There is no gall-bladder. The same distinguished comparative anatomist describes the pancreas as very long, thin, and having its left end attached to the lesser side of the first part of the duodenum. He observes, that it extends across the spine of the spine of the mesentery, and near to the pylorus joins the hollow curve of the duodenum, along which it is continued and adheres to the intestine, the duct entering this layer near the termination of the gut. In the Piked Whales the liver is a single and small; in the Porpoise it is subdivided into several distinct portions.

The following preparations, illustrative of the teeth and other digestive organs of the Cetacea, will be found in the Physiological Section of the First Report of the Royal Society of Surgeons in London: Nos. 319, 320, 321, are transverse and perpendicular sections of plates of whalebone, with the vascular basis or gum, &c., of the Piked Whale (Balaena boops, Linn.), No. 322 is a perpendicular section of a single plate of whalebone, in the Piked Whale, showing the outer and inner layers, &c. No. 323 is a perpendicular section of several plates of whalebone, with the intermediate substance and vascular nidi, from the upper jaw of a young Piked Whale. The plates are fringed with very small, very rigid hairs or bristles, which explains the passage in Aristotle (Hist. Anim. ill. 121), who, speaking of the Great Whale (mediumc, or, as Bekker reads it, δ μεθεν κρακάω), says: 'The Mysticetes have no teeth in its mouth, but have as hogs' bristles.' Nos. 324, 325 A, and 326, are sections of the jaws of the Porpoise, showing the teeth, their roots, gums, &c. Nos. 327, 328, are sections of the lower jaw, with teeth and sections of them of Delphinus tursio, Fabr. (small Bottle-nose Whale of J. Hunter), No. 329 is a section of the cavity of the stomach of the Piked Whale. No. 573 is a portion of the cavity of the stomach of some cetaceous animal. Nos. 574 and 575 are portions of the first and second cavities of the stomach of a Porpoise. Nos. 576, 577, 578, are portions of the cavity of the stomach of a Piked Whale. No. 579 is the injected stomach of a Porpoise, showing various cavities, &c. No. 730 is a portion of the rectum of a Porpoise injected. Nos. 740 and 741 are longitudinal sections of the termination of the intestinal canal of Delphinus tursio, Fabr., the last showing the large longitudinal and small transverse rugos of the lining membrane. No. 742 is a longitudinal section of the commencement of the rectum of Delphinus Boletus, Cuv. and No. 743 is a longitudinal section of the rectum and anus of the Piked Whale (Balaena boops, Linn.), showing the zigzag rugos, &c. No.
823 is a portion of the pancreas, of the duodenum, and of the hepatic duct of the same species; and No. 624 is a portion of the lining membrane of the hepatic duct of the same whale.

Circulating System.

Phylophagous Cetaceans.—The three Dugongs described by Professor Owen presented the same remarkable expanse of separation of the two ventricles of the heart, described by Sir Everard Home and Sir Stamford Raffles in the individuals examined by them, and observed by Rippell in the Dugong of the Red Sea (Halocere tabernacul.). Daubenton appears to be the first who noticed this condition of the heart in the herbivorous Cetaceans (from the genus Helocereus, and M.). Steller also described it in the genus which bears his name; but in that animal the apical cleft of the heart extended upwards only one-third of the way towards the base, whereas in the Dugong it reaches half-way towards the base.

Professor Owen found the foramen ovale completely closed, and the ductus arteriosus reduced to a thick ligamentous chord, permeable for a short distance by an eye-probe from the aorta, where a crescentic slit still represented the original communication. He states that in the smoothness and evenness of their exterior and their general form the aorticles of the Dugong resemble those of the turtle (Chelone), and that the appendice can hardly be said to exist in the right aorticle larger than the left. The primary branches from the arches of the aorta correspond in each specimen with Sir Everard Home's figure and description. There was only one superior cava, not two, as in the elephant; and the pulmonary veins terminated in the left auricle by a common trunk an inch in length.

As no mention had been made in the anatomical descriptions of the herbivorous cetaceans by Daubenton, Steller, Cuvier, Raffles, and Home, respecting the existence or otherwise of the extraordinary inferior and intervertebral arterial plexuses present in the true Cetacean, Professor Owen carefully followed out this part of the dissection, but could detect no trace of this very striking modification. Here again, he observes, in enunciating a general or fundamental proposition regarding Cuvier's Cetaceans, the herbivorous species must be exceptionally cited apart.

Zoophagous Cetaceans.—Professor Owen remarks that the Carnivorous Cetaceans do not participate in the structure of the heart above described with the Herbivorous species.

The following is John Hunter's description of the heart of the Whale:

"The heart is inclosed in its pericardium, which is attached by a broad surface to the diaphragm, as in the human species. It is composed of two auricles and two ventricles: it is more flat than in the quadruped, and adapted to the shape of the chest. The auricles have more fasciculi, and then pass more across the cavity from side to side than in many other animals; besides, the intercostals all anastomose, and in the left auricle two auricles and two ventricles: it is more flat than in the quadruped, and adapted to the shape of the chest. The auricles have more fasciculi, and then pass more across the cavity from side to side than in many other animals; besides, the intercostals, which are very large, and gives branches to this plexus; and when it has reached the abdomen it sends off, as in the quadruped, the different branches to the viscera and the lumbar arteries, which are likewise very large, in the supply of that vast mass of muscles which forms the tail."

Moreover, Hunter prepared with his own hands the two instructive specimens of the arterial plexiform reservoirs in the Porpoise noticed by Sir Everard Home.

Hunter's description was published in 'Phil. Trans.' 1787, and Professor Owen well observes that M. Brechet could only have known it by extract or reference, or he would have not stated that the structure in question had been seen by him in the whale. He says, "on pourrait être dès lors compté au nombre des faits acquis à la science," for the Professor remarks that he does not find in M. Brechet's paper any essential addition to Hunter's original account, either with respect to the observation of additional facts, or to the physiological inferences deduced from them.

M. von Baer, in his valuable observations on the subdivision of the brachial arteries and on other parts of the vascular system of the porpoise, does not consider it necessary to depreciate the labours of our great anatomist. The arterial plexus of the whales has also been noticed by M. Deaumolins, and by Dr. Barclay, Dr. Knox, and Sir Wm. Jardine.

Dr. Sharpey's Observations on the Anatomy of the Blood-vessels of the Porpoise were read to the British Association for the Advancement of Science, in the same year and one month later than M. Brechet's paper was read to the
French Academy. They only occupy the greatest part of a page in the Society's Report, but are sound.

With regard to the veins, Professor Owen points out that they are remarkable not only for their great capacity, which Hunter noticed, but also for their number and the immenseplexuses which they form in different parts of the body, and above all for the almost total absence of valves. To observe, has given a figure of the extensive venousplexus situated on the membrane investing the poas muscles, and these have recently occupied the attention of Breschet and Von Baer. The inferior and superior veins are not brought into communication by the vena cava, as in other Mammalia; such veins in the usual situation in the chest would have been subject to compression between the arterial plexuses and the lungs. The vena cava are therefore represented by two venous trunks situated in the interior of the vertebral canal, where theyreceive the intercostal and lumbar veins, and finallycommunicate with the superior cava by means of a short single large trunk, which penetrates the paires of the posterior and right side of the chest. Professor Owen concludes this interesting note to Hunter's 'Animal Economy' by clearing up the difficulty, which must have occurred to most ofaccounting for the fact so enormous an animal as the great whale being killed by such puny instruments as the harpoon and lance. The nature and structure of the veins in the cetacea, says the Professor, 'and the pressure of the sea-water at the depths to which they retreat when harpooned, explain the profuse and deadly hemorrhage which follows a wound that in other Mammalia would be by no means fatal.'

The following preparations in the Physiological Series of the Museum of the Royal College of Surgeons illustrate the circulating system in the whales:—No. 925, the appendix of one of the arteries of the Bottlenose Whale (Delphinus Dallisi, Cuv.), showing on a large scale the fleshy bundles, musculi pectorales, which assist in propelling the blood from the heart into the ventricle. No. 926, a large portion of the right auricle of the same whale. No. 927, a portion of the left ventricle of the same whale, showing the mitral valve, aortic-pulmonary orifice, and auriculo-ventricular, which last are seen attached to the ventricular surface of the valves, as well as to their margin. No. 927 A, the heart of a Porpoise (Phocena communis), showing the completely closed foramen ovale, absence of any trace of an Eustachian valve in the right auricle, and ductus arteriosus so obliterated as to admit only the passage of a small bristle. Nos. 132 and 133 (dry preparations), two instructivestripes, injected by Hunter, of the peculiar arterialplexiform reservoirs in the Porpoise.

Phytophagous Cetacea.—Professor Owen states that the peculiar form, structure, and position of the lungs have been so accurately described and figured by Raffles, Home, and Rippell, that he has only to observe the close agreement with these statements which the following specimens present in the three Dugongs dissected by him. Dunbanton and Humboldt, he remarks, describe and figure a precisely similar condition of the respiratory apparatus in the Manatee. Steller, he adds, describes the same extension of the lungs in the Balaenoptera and other Cetacea, though the lungs in the bird, without their fixation in the paires of the chest, so characteristic of that class. Professor Owen is of opinion that the Chelonian reptiles, perhaps, offer a closer resemblance to the herbivorous Cetacea in this respect, and he notices it as a very remarkable, that the lungs larger in the Dugong than in any other mammals. In the carnivorous Cetacea, the air-cells, he observes, are remarkably minute, and the lungs more compactly shaped and lodged in a shorter thorax.

'Existing,' contends Professor Owen, 'as both the herbivorous and carnivorous Cetacea do, under such peculiar circumstances—as air-breathing animals constantly dwelling in an element the access of which to the lungs would be immediately fatal—it might be supposed that the mechanism of the lungs, or entry to the diaphragm, would be similarly modified in all the species, in order to meet the contingencies of their aquatic existence. But we can as little predicate a community of organization in the structure of this part, as of the circulating or digestive system in the Cetacea. For, although the Dolphin present, in fact, the two extremes in the Mammalian class, in the development of the epithlottis, which is one of the chief internal characteristics of that class. In the Balaenoptera and the Delphinus, in particular, it is remarkable for its great length, and in the Dugong it can hardly be said to exist at all.'

Professor Owen, after giving a minute and accurate account of the larynx, thus proceeds:—'Amongst the two almost or all the animals of this order, we have observed that it is those which subsist on the lowest organized animal substance, as the Baleenidae, which approach the nearest to the herbivorous species, in having the additional complexity of the cæcum; and it is interesting to find that the same is the structure of the larynx. The epithlottis and arytenoid cartilages, for example, are relatively shorter in the Balaenoptera than in Delphinus; and, as Mr. Hunter has observed, they are connected together by the membranes of the larynx only at their base; and not wrapped together as in the Dugong, a circumstance so far as the oppos, as in the Dolphins. In the Balaenoptera also, the apices of these cartilages are not expanded, as in the Dolphins, but diminished to an obtuse extremity. These points of resemblance to the condition of the larynx in the Manatee and Manatus, as well as the comparative size of the heart and other organs in the Balaenoptera, is evident in the Humpback Whale, at least in the Balaenoptera, or in the Piked Whale, or in the Humpback, or in the Dugong, we find a single piece, in both of these, as in the Balaenoptera and Balanoptera, published by Professor G. Sandifort, preclude the necessity of further dwelling upon.'

The diaphragm, lungs, bronchi, and trachea present in the Zoophagous Cetacea, secondary modifications, but important differences are exhibited in the nostrils, which serve to conduct the air from the atmosphere to the lungs. The necessity for the act of spouting seems to have led to the obliteration of the organ of smelling, and to the formation of a new organ, the sphenopalatine sinus, which surrounds the nostril and serves for the passage of air. Although this organ has only been observed recently in the Dolphins, it is probable that the apparatus in all the Zoophagous cetacea is the same.

If, says Baron Cuvier, we trace the osseous upwards, we find that when it arrives opposite the pharynx it appears to divide into two passages, one of which is continued onwards to the mouth, while the other is continued for the nose: mucous glands and fleshy fibers surround the last mentioned passage. Some of these are longitudinal, and arise from the

* * * Nieuwe Verhandelingen der Koninklijke Akademie. p. 224, pl. 1—9.
ference of the posterior orifice of the bony nostrils, and descend along that canal to the pharynx and its sides; the others, which are annular, appear to be a continuation of the proper muscles of the pharynx. The larynx rises into this passage in a pyramidal form, and the annular fibres have the power of constricting it. Muscular follicles, which pour out their secretion by conspicuous extrareticular orifices, prevail in this part. When the lining of the nasal passage has reached the vomer, it becomes of a peculiar texture, thin, smooth, and black, is apparently destitute of vessels and nerves, and very dry. A fleshy valve closes the two bony nasal canals at the upper or external orifice. It is formed of two semicircles attached to the anterior edge of that orifice; which it shuts by the agency of a very strong muscle lodged above the intermaxillary bones. To open it, there is a necessity for some foreign body to press against it from below; and when it is closed, it debars all communication between the nasal passages and the cavities above them, which cavities are two large membranous pouches formed by dark mucus skin, and very much wrinkled when empty; but when distended, they become of an oval shape, which in the Porpese is about as large as a common wine-glass. These two pouches lie beneath the integument in front of the nostrils, and communicate with an intermediate space immediately above those nasal organs, whose external orifice is a transverse semilunar slit. Strong fleshy fibres expand and cover the whole upper surface of this apparatus, radiating from the entire circumference of the cranium, uniting above the two pouches, and adapted for compressing them forcibly. Now we will suppose that the cetacean has taken into its mouth water which it wishes to eject: it first sets the tongue and jaws in motion as if it were about to swallow the water; but, shutting its pharynx, it forces the water to ascend into the nasal passages, where the annular fibres above mentioned accelerate its progress till it raises the valves and distends the membranous pouches above. The water, when once in the pouches, can be retained till the animal wishes to spout. When that wish is present, the cetacean closes the valve, and expels the descent of the water into the nasal passages, and forcibly compresses the pouches by means of the muscular expansion which overspreads them. The water, compelled then to escape by the narrow semilunar aperture, is projected to a height which corresponds to the amount of the pressure applied.

Vertical section, exhibiting the tongue, larynx, and nostrils of the Porpese (from the Physiological Series (Mammalia, Chirot.). vol. ii. p. 109.)

In the ease of the Spermaceti Whale, it appears that the animal occupies about a seventh of its time in breathing; and when it rises after long intervals, an enormous column of air must rush into the lungs and aerate a vast quantity of blood for the reservoir described by Hunter. In ordinary mammals, man and the quadrupeds for instance, respiration is momentary. A fleshy valve is inserted at the upper extremity of the snout: in the Whalebone Whales it is double, opening towards the summit of the head, as in the Dolphins, in a crescentic form whose convexity is sometimes anterior and sometimes posterior.

The following preparations illustrate the respiratory system of the Whales, in the Museum of the Royal College of Surgeons:—Nos. 1122, 1133, small portions of the line of a Porpese; No. 1166, the longitudinal section of the head of a Porpese, showing the pyramidal larynx project.ed into the posterior nasal and embraced by the margin of the soft palate, which surround it like a sphincter and cut off all communication between the mouth and nostrils; No. 1157, a longitudinal section of the tongue, pharynx, and larynx of a Porpese; No. 1109, the orhyoid and larynx of a Porpese; No. 1182, for larynx and pharynx of a Dolfinus (Dolphinsurs, Fabr.); both these show the division of the fauces into two passages for the course of the food in defluxion on each side of the pyramidal larynx.

For a very luminous account of the larynx and blow-hole or air-passage in this tribe, see the paper of John Hunter on Whales, above quoted, in Phil. Trans. (vol. 1xxxvii., p. 416), 1789.

Uroptotic System.

Professor Owen observes, that if we were acquainted with the structure of the urinary organs of the herbivorous Cetacea, as it is exemplified in the Dugong alone, we should have to establish as a marked distinction in the species of the manatees, Manatee, and Echidna, in the enclosed organic systems. Instead of the numerous and minute lobuli or renules into which the kidney is subdivided in the Dolphins and Whales, it presents in the Dugong a simple compact form with an unbroken external surface, where the organ is compressed into a series of eleven mammmillae, which project into a single elongated cavity or pelvis, from which the ureter is continued. In the Northern Manatee however, Steller, whose accuracy Professor Owen justly notices, describes the kidney as a series of minute lobules, or renues, and this is, as a matter of course, the case in the Manatus americanus, merely notices the kidneys as oblong, and placed opposite to each other; nor does his figure give any indication of lobulated structure; neither does Sir Everard Home mention such structure in the Anatomy of the Manatee, in Phil. Trans. (1821). The want of uniformity in the structure of the kidney in the herbivorous Cetacea is however, Professor Owen adds of less moment with reference to their natural affinity, since in the Pachyderm we find some species with the Retinae, and, though in a less degree, the Elephant, presenting a subdivided kidney; while others, as the Tapir and Hog, have it entire.

In the fossa of the Dolphin, according to Müller, the lobules of the kidney consist of a large number of convoluted uriniferous ducts extending from the apex to the circumference of the lobule: the intertwinnings of the tubuli are greatest in the intercostal portion. It is a curious fact, Professor Owen remarks, that the supra-renal gland in the Porpese presents a certain resemblance to the kidney in its lobulated exterior; but, he adds, the analogy extends no farther, for on making a section of this part it was found to consist of the usual continuous compact substance.

In the Museum of the Royal College of Surgeons, No. 1266 is the right kidney of a young Porpese injected, showing the component renules; No. 1267, 1268 are transverse and longitudinal sections of the kidney of the Piked Whale (Balana hoopa, Linn.); No. 1290 is the supra-renal gland of Dolphines and enamel; and No. 1291 shows the kidney and supra-renal gland of a Porpese. (Physiological Series.)

Generative System.

The organs of generation, being those which are most intimately related to the function of an animal, have always been regarded by Professor Owen, and most justly in our opinion, as affording very clear indications of its true affinities. We are the least likely, says he, in the modifications of these organs to mistake a merely external and superficial likeness, but they have, as it were, the well-known fact that the true Cetacea have no trace of vestigial seminales; but he found these bars present, and of large size, in the Dugong. The case deferentia were short and disposed in irregular convolutions. Each crus penis was
attached to the lower expanded extremity of the ischium, which were anched to the ilia on each side. In the smaller cetaceans it is diminished to a proportionate size, as its extraordinary development in the Dolphin, as observed by Professor Owen, in the retractor penis, runs along the sides to the under surface of that organ; whereas in the Dugong the corresponding muscles are inserted into the dorsum penis, as in the elephant: they meet, be adds, and join in a strong tendon half-way between the crus and the glans penis. Proceeding in his inquiry, Professor Owen observes that the true Cetacea the body of the penis consists of a single corpus cavernosum, grooved above for the passage of the vena dorsalis, and deeply excavated below for the lodgment of the urethra; a condition of utterance which presents a marked deviation from the ceteal structure of the two previous parts, which presents in a transverse section a division of the corpus cavernosum into two lateral portions, the lateral ligamentous septum, as in the Pachyderma; the vascular mass which fills the tube, in each whale, bears a greater proportion to the surrounding ligamentous structure than in the true Cetacea. The testes, observes the Professor in conclusion, are abdominal in the Dugong, as in the rest of the Cetacea; but, he adds, they also have a similar position in the Elephant.

John Hunter remarks that the organs of generation of this order of animals come in both sexes nearer in form to those of the Ruminants than of any others; and this similarity is one of the marks by which the female their situation varies on account of the modification of the external form of the body.

The female organs in the Rytina have been described by Steller, and Sir Everard Home has given an account of them in the tongue, of the_Whale_.

Hunter, in his paper on Whales has entered particularly into the structure of those of the Zoophagous cetaceans.

The copulation has been alleged to be carried on in an upright position with the heads of both sexes at the surface; the small formation of the body would not admit of the female taking that position, and the organ is thus in a perpendicular position.

If, by using the vulgar word _perineum_, we may denote the region between the thighs and the body; the external urethra, the vagina, and the hymen, as the parts which have to be formed for the organ of generation; the men of the Whale is an organ which is the seat of these functions, and is the organ of generation.

It is also the organ of smell, which is capable of but slight motion.

But it has been doubted whether the Zoophagous Cetacean are endowed with a special organ for the enjoyment of this sense. No fossil nor conical papillae are preserved in the Dolphin, but the Piged Whale. It was at once supposed, therefore, he remarks, to account for the manner in which such animals smell the water; and why the others should not have had such an organ, which seems to be peculiar to the large and small Cetacean whales (Balene mysticetes and Baleno optera rostrata, in which to which has, he adds, is extremely small, when compared with that of other animals, as well as the nerve which is to receive the impression.

Nos. 1841 to 1846; both inclusive, in the series above quoted, illustrate the nasal passages, &c. in the Zoophagous Cetaceans.

Taste.—The complicated and delicate structure of the tongue in the Phyllodochus cetacean indicates the presence of taste, although the tongue is capable of but slight motion.

John Hunter, in his paper on Whales, which is the organ of taste, is also endowed with the sense of touch. He found the tongue in the Porpesse and Grampus firm in texture, composed of muscle and fat; and pointed and serrated on its edges, like that of a hog. In the Spermaceti Whale, however, he says, it was almost as soft as that of a feathered animal. The Piged Whale it was but slightly raised, hardly having any lateral edges, and its tip projecting but little, yet, like every other tongue, composed of muscle and fat. He supposes that the tongue of the large Whalbone Whale rises in the mouth considerably; the two jaws in the middle being kept at such a distance on account of the whalbone, so that the space between, when the mouth is shut, must be filled with the tongue.

Nos. 1846 to 1848; both inclusive, illustrate the organization of the tongue in the Zoophagous Cetacean (Delphinus, Balena, and Hyperoodon), in the Physiological Series of the Museum of the Royal College of Surgeons.

Sight.—The eye in the Herbivorous Cetaceans only is provided with a nictitating membrane, as the Zoophagous or Spouting Cetacean has no lacrimal glands, but the lids are furnished with glands for a mucous secretion adapted for lubricating the sclerotic coat.

John Hunter states that the eye in this tribe is constructed upon nearly the same principle as that of quadrupeds, differing however in some circumstances; by which it is probably better adapted to see in the medium through which the light is to pass. It is upon the whole small for the size of the animal. The lids have but little motion, and are not provided with a nictitating membrane, which in quadrupeds, but rather of the common adipose membrane of the body; the connection however of their circumference with the common integuments is loose, the cellular membrane being less loaded with oil, which allows of a great fold being made in the skin, and of the eye being opened the eyelids. This is not to an equal degree, he adds, in them all, being less so in the Porpesse than in the Piged Whale. A detailed account of the anatomy of the eye in whales will be found in Hunter's_ Illustrations of the Figures of the College_. No. 1777 A exhibits the eyeball and characteristic nictitating membrane in the Dugong.

Nos. 1773 to 1777, both inclusive, illustrate the eyeball and its appendages in the Porpesse, Dolphin, and Piged Whale.

Hearing.—There is no external concha; but the ear is constructed much upon the same principle as in the qu
ped; there are however certain differences which the reader will find set forth in Hunter's paper. The sense seems to be fairly developed, and Whale-fishers experience no small difficulty from the warning given by both eye and ear. It has however been stated that the Greenland whale, though not about a mere sense of hearing, remains insensible to the report of a cannon.

In the Physiological Series of the Museum of the College, the following preparations illustrate the organ of hearing in the Whales:—No. 116, section of the tympanum of Balena mysticetus steered in acid; and No. 1582 to 1586 B, both inclusive, affording a striking example of the extent of John Hunter's researches relative to this organ in the Zoophagous Cetaceans.

Touch.—The sensation of touch must be lively, though it is commonly believed that the common Dolphin, notwithstanding its delicate epidermis, is not very sensible to tactile impressions. M. Breschet and M. Roussel de Vaurèze distinguish the following constituents in the skin of the Cetaceans:—1. Derm, or corium, a dense fibrous cellular texture, which contains and protects all the other parts of the skin. 2. The papillary bodies, consisting of papilla, covered by the derm. 3. The cutaneous apparatus, consisting of soft, elastic, spiral canals, which extend through the entire thickness of the derm, and open in the interspace of the papilla, which is closed, generally, by a small epidermic valve. 4. The inhalant apparatus. 5. The mucous apparatus. 6. The colorific apparatus.

According to Hunter, the reticular network containing the blubber, which is described by him as fine in the Porpoise, Spermaceti, and large Whalebone Whale (Balena), and coarse in the Grampus and small Whale-bone Whale (Balenosperma), forms part of the skin. See above, p. 257. (Taste).

The preparations illustrative of the organs of touch, besides those noticed under the head of Taste, in the Physiological Series of the Museum of the College, are Nos. 1463, 1404, 1405, 1406, exhibiting a section of the tail of a Porpoise; a cuticle in the whale, removed, to show the villi of the cuta, a portion of the true skin of a whale, a section of the same, and a portion of the plicated integument from the under part of the neck or thorax of the Piked Whale (Balena loops, Linn.), showing the puckering of the softer skin in the interspaces of the longitudinal folds.

Natural History.

The natural history of the Phytophagous and Zoophagous Cetaceans, even moderately followed out, would of itself be a large subject. Our space will not permit us to give more than a mere descriptive sketch of some of the forms of this great and highly interesting order. The same reason has compelled us to omit much valuable information relative to their organization; but we have endeavored in our compressed abridgment to touch on most of the leading points.

Phytophagous Cetaceans.

We have treated of this division under our present title, because the animals which it comprises would be looked for here, in consequence of the general position assigned to them by zoologists; but it is impossible to study their organization and habits without perceiving that they do not belong to the true Whales: they are, in short, Aquatic Pachyderms.

It is not indeed surprising that they should so long have been confounded with the Cetaceans: for their general appearance and horizontal tail, joined to the difficulty of distinguishing either with those or the Walrus, notwithstanding their aquatic habits, led naturally to their being placed in the same order with the true zoophagous whales. But with external form almost all resemblance ceases; these phytophagous mammals are such as they ought to be, referred to a separate group, there will not be, so far as discovery has hitherto gone, any such animal as a phytophagous whale.

The short and thick neck, fin-like fore-legs, want of hind-legs, caudal tegumentary fin, smooth, naked, and almost hairless integument, are all modifications of external form by which the Dugongs and Manatees are adapted to play their part in the water: but the kind of part, says Professor Owen, which they are to play in that element depends on organic characters which mainly, if not exclu-
